tic shock, the displaceable 14C-fluphenazine binding was restricted primarily to the subfraction containing synaptic membranes. This suggests that the displaceable 14C-fluphenazine-binding sites are consistent with postsynaptic dopamine receptors in the striate region; however, regional studies of the brain revealed a rather uniform pattern of displaceable <sup>14</sup>C-fluphenazine binding (Table 2). Although most binding occurred in the striate region and the cerebral cortex, there was no correlation between the regional concentration of dopamine and the displaceable 14C-fluphenazine binding capacity. The displaceable binding to peripheral organs and tissues was much less than that observed in brain tissue, with the liver and a sample of striated muscle having the lowest binding capacity of the tissues studied. The regional and subcellular distributions of displaceable fluphenazine binding were similar when the concentration of <sup>14</sup>C-fluphenazine in the incubation medium was reduced to 0.5 µM, the limit of sensitivity of the assay system.

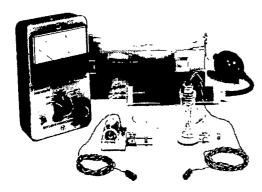

Table 3 Relative potencies of drugs in reducing displaceable <sup>14</sup>C-fluphenazine binding to homogenates of the striate region of rat brain

Drug ·	$ED_{50}(\mu M)$	No effect	(mM)
Fluphenazine		Acetylcholine	100
Thioridazine	8.4	GABA	100
Chlorpromazine	32	Glutamic acid	100
Haloperidol	35	Glycine	100

Promethazine	430	Thiopentone	10
Imipramine	450	Diazepam	10
Benztropine	460	Chlordiazepoxide	10
Propranolol	500	Dopa	100
Dichlorisoprenaline	600	Homovanillic acid	100
Tranylcypromine	900	3-Methoxy-4-hydroxyphenyl	
•		glycol	100
Dexchlorpheniramine	1,000	Adrenochrome	100
Phentolamine	1,200	Atropine	1
Phenoxybenzamine	1,900		
Methysergide	4,800		
d-Amphetamine	7,500		
Clonidine	17,000		
<i>l</i> -Noradrenaline	28,000		
Apomorphine	29,000		
Dopamine	30,000		
6-Hydroxydopamine	34,000		
I-Adrenaline	35,000		
Histamine	40,000		
Tyramine	42,000		
Serotonin	42,000		
Isoprenaline	44,000		
Normetanephrine	51,000		
d-Adrenaline	55,000		
Metanephrine	61,000		

The values shown represent the mean of two or three log-probit determinations using four concentrations of the drug.

In most regions of the brain the predominant biogenic amines are noradrenaline and serotonin and in all brain regions and subcellular fractions of the striate or cerebellum these amines could displace bound 14C-fluphenazine with potencies very similar to that of dopamine (Table 3). Other putative neurotransmitters, such as acetylcholine,  $\gamma$ -aminobutyric acid (GABA), glutamic acid and glycine, were inactive in this regard. The displacement of  $^{14}$ C-fluphenazine from binding sites by catecholamines, serotonin, their metabolites and related amines does not necessarily mean that these amines will have agonist activity at such sites; they may be very weak antagonists. This hypothesis is supported by the finding that various drugs, including α and β-receptor blockers and tricyclic antidepressant compounds, displace bound 14C-fluphenazine (Table 3); in this respect they are not as potent as compounds with known antipsychotic activity. The phenothiazine antipsychotics fluphenazine, thiorodazine and chlorpromazine were the most potent in displacing bound <sup>14</sup>C-fluphenazine, whereas pro-

## For the Measurement of Resistance to Water Loss by Intact Leaves

# DIFFUSIVE RESISTANCE I

This new instrument is designed for portability, ease of operation, durability and accuracy.

#### **SPECIFIC FEATURES**

- · Two sensitivity ranges
- · Rapid meter response
- · Lightweight metal case
- · Calibrated thermistor for leaf temperature measurements
- Battery life exceeds 200 hrs.
   Meter circuitry independent of ambient temperature

# Oertling + Cahn

We are pleased to tell you that Oertling have taken over the sole UK Agency for Cahn Instruments, of Paramount, California.

Cahn fill well a particular niche in the world of weighing: "Micrograms without tears" you might call it.
Whereas conventional micro-balances need special

Whereas conventional micro-balances need special setting-up, special environments and a fair degree of operator skill, Cahn balances need none of this.

# weighing family.

# R100 Recording Electrobalance R

Top left, with weighing mechanism in the symmetrical glass envelope, control module alongside, and optional pen recorder (below).

High capacity, 100g. Sensitivity, 0.5µg.

Rapid response, to weighing in vacuum up to 10<sup>-6</sup> torr, or under controlled atmospheres, including corrosive gases.

With push-button range selection, pushbutton taring, a panel meter to read sample weight and weight change, and an automatic range extender covering up to ten chart

A special RG version is also available with 100% over-range, i.e. up to 19999. a large range of accessories for TGA absorption work, magnetic susceptibility, particle size analysis, density measurement

## 4100 Manual Electrobalance

This page, centre.

The most popular Cahn model; a direct reading micro-balance that can give a complete reading in a few seconds.

No wonder it's used for Lunar dust, air pollution samples, etc. etc.

Robust, portable and very easy to use. Just put the sample on the pan.

Capacity, up to 2.5q.

Four weight ranges, 2mg, 20mg, 200mg and 10000mg.

Sensitivity on 2mg range, 0.1µg. 4-digit electronic display read-out, with

Automatic decimal position, with no chance of misreading. BCD output for computer or optional Cahn printer.

Models GRM and G-2, without digital display, also available at lower cost.

# DTLToploading Electrobalan-

A very versatile direct-reading bala with large three-digit electronic display Capacity 10g.

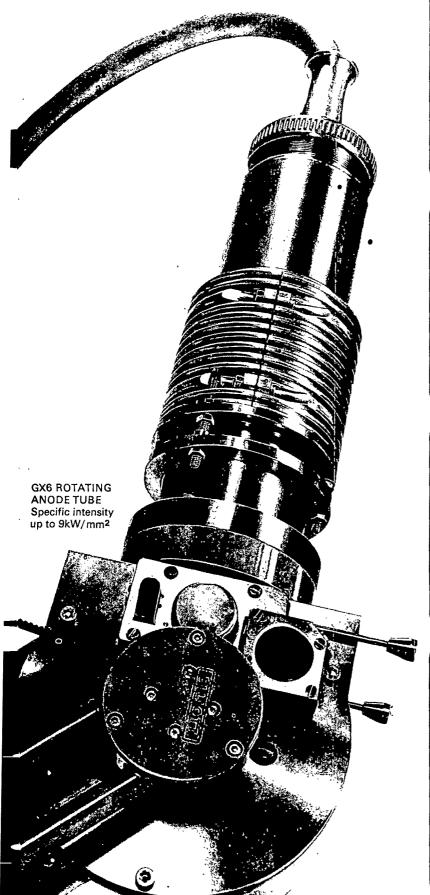

Sensitivity 0.1mg (0.01mg optional) Two weight ranges, 100mg and 100 0-10 volt analog output for records DVM, with BCD optional.

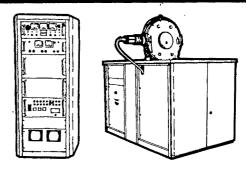

Up to 15 samples per minute can b weighed, in all kinds of hot, dry or adverenvironments; once the sample is on th you can get a reading in as little as half: second.

Also available, as RTL, without elec display.

## Elliott Neutron Division Marconi-Elliott Avionic Systems Ltd

Elstree Way, Borehamwood, Herts., England. Tel: 01-953 2030 - Telegrams: Elliotauto Borehamwood Telex: 22777 Member of GEC-Marconi Electronics Ltd methazine, a phenothiazine with weak antipsychotic properties, was about 100 times less active than fluphenazine. All compounds tested that possessed antipsychotic activity could displace bound 14C-fluphenazine in the striate region and cerebellum and there was a potency correlation between these two effects. A similar correlation exists between the clinical efficacy of anitpsychotic drugs and their ability to block the activation of adenyl cyclase by dopamine in selected brain regions<sup>1,2</sup>. Although dopamine did have affinity for fluphenazine binding sites, the variety of biogenic amines and related compounds that could displace bound fluphenazine in all brain regions suggested that dopamine receptors were not specifically labelled at the concentration of fluphenazine used, which is higher than that required to block the dopamine receptor of adenyl cyclase<sup>1</sup>. Therefore, although my studies support indirect evidence that antipsychotic drugs may act by blockade of receptor sites for biogenic amines, they also suggest that this action is not confined to striatal dopamine receptors at postsynaptic sites.

#### Tyrosinase in the skin of albino hamsters and mice

Measurements of tyrosinase (EC 1.10.3.1) in animals with oculocutaneous albinism have led to contradictory conclusions. Using the incorporation of <sup>14</sup>C-DL- or L-tyrosine into melanin, one investigator found no, or questionable, activity in albino mouse skin1,2 while another3 reported very low, but significant activity in particles from albino mouse eyes treated with Triton X-100. When the production of <sup>3</sup>HOH from 3,5-<sup>3</sup>H-L-tyrosine was used as an assay, albino hamsters' were found to have no detectable activity, while albino rats' were reported to have minimal, but real activity. We report clear evidence for a tyrosine hydroxylase with tyrosinase characteristics in the skin of two strains of albino hamster and one strain of albino mouse. The method used permits quantitative comparison with tyrosinase in pigmented skin. A distinct dopa oxidase is present in extracts of albino mouse.

Tyrosine hydroxylating activity of tyrosinase was measured<sup>4</sup> by incubating (at 37° C) 3,5-3H-L-tyrosine, 1 μmol (2 to 3×10<sup>6</sup> d.p.m.); L-3,4-dihydroxyphenylalanine (dopa), 0.15 µmol; sodium phosphate (pH 6.8) or sodium pyrophosphate (pH 7.4) 20-30  $\mu$ mol; and enzyme in a total volume of 1.25 ml. Where indicated in the Tables dopa was omitted. When diethyldithiocarbamate (DDC) was added the components were incubated together for 1 h at 37° C before addition of tyrosine and dopa. The blanks were reactions without enzyme; blanks have been subtracted from observed values to obtain the values reported (averages

Table 1 Tyrosine hydroxylation by skin homogenates from T<sup>5</sup> albino and Syrian golden hamsters

Experiment and	Dopa	DDC	3HOH

	+	+	40

In both experiments skin from 7-d-old hamsters was homogeni in 0.02 M sodium pyrophosphate (pH 7.4) (1 g skin per 3 ml). 7 standard assay mixture for tyrosine hydroxylation was used exce where indicated, dopa was absent and DDC was added. The blas were equivalent to 9.0 nmol h<sup>-1</sup> g<sup>-1</sup> (experiment 1) and 60 nmol h<sup>-1</sup> (experiment 2).

of duplicates). 3,5-3H-L-tyrosine was purified by high volta paper electrophoresis6 and 3HOH in the stored 3H-tyrosi was removed by evaporating the solution to dryness imme iately before use. Boiled homogenates gave the same resu as non-enzymatic controls.

Another assay for tyrosinase was based on the oxic tion of dopa to dopachrome observed spectrophotometrica at 475 nm (ref. 7). A unit of tyrosinase is the amor catalysing the formation of 1 µmol of dopachrome min

Two strains of albino hamsters were used (Lakevi Hamster Colony, Newfield, New Jersey). TWA is oculocutaneous albino with no black areas while MI is similar but the adults develop pigmented skin in f ears. AKR/J albino mice were obtained from the Jacks Laboratory. The animals were killed between ages 5 and 7 either by decapitation or quick freezing. The body sk were frozen until used.

Antiserum against homogeneous hamster melanoma ty sinase8 was raised in rabbits. The antiserum was titred follows. Antiserum (0.10 ml, diluted with 10% norn rabbit serum (NRS) made up in 0.05 M sodium bors (pH 8.5)) was incubated at 37° C for 1 h with tyrosins (0.02-0.2 U) and sodium phosphate (pH 6.8), 30-60  $\mu$ m in a volume of 1 or 2 ml. The solution was then centrifug at 105,000g for 1 h and a portion of the supernatant vassayed for tyrosinase by either the 3HOH or the do; chrome method. The enzyme remaining in the supernata

Table 2 Dopa dependency and DDC inhibition of tyrosine hydro lation by supernatant fractions of skin from TWA and MHA albi hamsters

Experiment and type of hamster	Dopa (1.2×10 <sup>-4</sup> M)	DDC (1×10 <sup>-3</sup> M)	Time of incubation (h)	³HOH (nmol g
•	+		6	8.3
(1) TWA albino		_	6	0.8
•	+	+	6	. 0
(2) TWA albino	+	_	6	13.3
• •	+	+	6	0
	+	_	3	9.2
(3) MHA albino		_	3	2.5
, ,	+	+	3	0
(4) MHA albino	+	_	6,5	11.7
•	·	_	6.5	6.3

Homogenates of albino hamster skin were prepared as described Table 1. After centrifugation at 105,000g for 1 h the supernata were dialysed against 0.003 M sodium phosphate (pH 6.8) and stirt with calcium phosphate gel (1.75 mg gel per mg protein) for 1 h. mixtures were centrifuged at 10,000 r.p.m. for 20 min and the sup natants were assayed. The standard assay procedure for tyros hydroxylation was used, with dopa absent and DDC included what appropriate. Blanks were equivalent to 5.8 nmol g<sup>-1</sup> (experiment 4.0 nmol g<sup>-1</sup> (experiment 2), 7.5 nmol g<sup>-1</sup> (experiment 3), a 4.6 nmol g<sup>-1</sup> (experiment 4). was always compared with a control incubated only with NRS. No loss of activity was seen in control samples.

The tyrosine hydroxylating activity of TWA hamster albino skin (Table 1) was at a level which was missed previously. Table 1 also shows that hydroxylation by TWA homogenates was not dependent on dopa and not inhibited by DDC as was tyrosinase in homogenates of pigmented hamster skin. Similar results were obtained from homogenates of MHA albino skin. Centrifugation of his homogenate at 105,000g for 1 h gave a supernatant which had 10–15% of the tyrosine hydroxylation activity. Treatment of these supernatant fractions with calcium phosphate gel gave fractions which were dependent on dopa and inhibited by DDC, properties typical of tyrosinases (Table 2).

The AKR/J albino mouse skin homogenate had a tyrosine hydroxylating activity of 0.2  $\mu$ mol h<sup>-1</sup> g<sup>-1</sup>, independent of dopa and not inhibited by DDC. Although little or no activity was released by homogenisation in buffer alone, 10–25% of the activity was extracted with Igepal CO-630 (nonylphenoxypoly (ethyleneoxy) ethanol; GAF, New York.) The data in Table 3 show that the activity in the calcium phosphate fraction was inhibited by DDC and that in the ammonium sulphate fraction was dependent on dopa.

An immunological demonstration that tyrosine hydroxylation belonged to a tyrosinase-like protein was based on the use of antibody against tyrosinase. This is clearly shown in Table 4. The activity in skin from each of the three albino strains was bound to antibody and sedimented during centrifugation. This led to the loss of tyrosine hydroxylation activity from the supernatant.

Tyrosinase possesses both tyrosine hydroxylating and dopa oxidising activities, the latter property leading to the formation of melanin. Surprisingly, it was possible to separate a dopa oxidase from the tyrosine hydroxylase as follows. Supernatant from a AKR/J homogenate, 10 ml (equivalent to 3.3 g skin), prepared with Igepal, was loaded on a 2×5 cm column of DEAE-cellulose or CM-cellulose. The resin was washed with 0.003 M sodium phosphate **◄**(pH 6.8), 150 ml (fraction 1, containing most of the Igepal) and 0.1 M sodium phosphate (pH 6.8), 160 ml (fraction 2). The fractions were concentrated under N2 about 15-fold with an Amicon PM-10 filter. Qualitatively the results from both resins were the same. Fraction 1 from each column retained the tyrosine hydroxylating activity, while fraction 2 had none. While fractions 1 formed some pigment, however, the fractions 2 became quite dark during incubation, indicating that these fractions retained most of the dopa oxidase activity. In one experiment, 0.8 ml of fraction 2

Cable 3 Dopa dependency and DDC inhibition of tyrosine hydroxylaion by supernatant fractions of skin from AKR/J albino mice

Experiment	Dopa	DDC	³НОН
	$(1.2 \times 10^{-4} \text{ M})$	$(1 \times 10^{-3} \text{ M})$	$(nmol g^{-1})$
1) Calcium	` + ´	` _ ′	180
phosphate gel	+	+	5.0
fraction		<u>-</u>	162
2) Ammonium	+	_	44.4
sulphate fraction		-	13.8

AKR/J albino mouse skin was homogenised as in Table 1 in buffer ontaining 1% by volume of Igepal. After centrifugation at 105,000g or 1 h, the supernatant was treated with calcium phosphate gel as tescribed in Table 2. The supernatant was then treated with amaonium sulphate to 80% saturation. On centrifugation of this nixture the protein precipitate remained suspended with Igepal at the op of the tube. This protein-Igepal mixture was separated and disolved in 0.05 M sodium phosphate (pH 6.8) to give a milky suspension which was dialysed against the same buffer. In experiment 1 the alcium phosphate gel fraction was used; in experiment 2, the immonium sulphate fraction. The standard assay for tyrosine sydroxylation (6 h incubation) was used with dopa absent and DDC colleded where appropriate. Blanks were equivalent to 15 nmol g<sup>-1</sup> (experiment 1) and 3.5 nmol g<sup>-1</sup> (experiment 2).

Table 4 Binding of tyrosine hydroxylating activity in extracts of TWA and MHA albino hamster and AKR/J albino mouse skin to anti-tyrosinase serum

Experi- ment	Extract source	Equivaler amount of		NRS	³HOH in aliquot	Activity lost from
(1)	TWA ·	skin (g)			counted (d.p.m.) 476	superatant (%)
(1)		4.0	+	+ - +	197 1,732	58
(2)	AKR/J	0.8	+	<del>-</del>	1,732 0 483	100
(2)	Hamster (		+	· <del>-</del>	157 9,480	77
	melanoma		+	_	4,675	51

Calcium phosphate gel extracts of skin from TWA albino hamsters (experiment 1) and MHA albino hamsters, AKR/J albino mice, and hamster melanoma\* (experiment 2) were incubated with antiserum to hamster melanoma tyrosinase (final concentration 1:3,500) or an equivalent amount of NRS. The solution contained 2 mg (experiment 1) or 4 mg (experiment 2) bovine serum albumin, sodium phosphate buffer (pH 6.8), 60 µmol, in a final volume of 1.14 ml (experiment 1) or 1.24 ml (experiment 2). The incubation was for 1 h at 37° C followed by 16 h at 4° C and then centrifugation at 100,000g for 1 h. Supernatant (0.5 to 0.8 ml) was assayed for residual tyrosine hydroxylating activity by the standard method. Time of incubation was 6 for the albino skin extracts and 3 h for the melanoma tyrosinase. Blank values were 400 d.p.m. (experiment 1) and 555 d.p.m. (experiment 2).

oxidised 1.8 nmol dopa min<sup>-1</sup> but the fraction had no tyrosine hydroxylating activity. Hamster melanoma tyrosinase, possessing the same dopa oxidase activity, hydroxylated 16 nmol tyrosine h<sup>-1</sup>.

An inhibitor of the dopa oxidase reaction of tyrosinase was present in fraction 1—0.40 ml completely inhibited dopa oxidation by melanoma tyrosinase.

Skin from newborns of all three albino animals can hydroxylate tyrosine at a rate 2-3% that for the corresponding pigmented variety (Syrian golden hamster4 and C57BL/6J mouse<sup>9</sup>). The amount solubilised by homogenisation alone (hamster) or by Igepal treatment (mouse) amounts to about 10% of that assayed in the homogenate. Further purification gives fractions which are dopa-dependent, inhibited by DDC and bound by anti-tyrosinase serum. Whether all the activity in the homogenates relates to tyrosinase cannot be decided yet. It seems unlikely that any of it is the result of a tetrahydropteridine-dependent tyrosine hydroxylase because even the crude adrenal medullary enzyme10 exhibits an absolute requirement for a pteridine cofactor. The absence of dopa-dependency could be explained by the presence of elevated levels of dopa or some other nonspecific reducing agent. The lack of inhibition by DDC cannot be readily explained. One investigator<sup>3</sup> inhibited albino eye tyrosinase with  $1 \times 10^{-2}$  M DDC, while another<sup>5</sup> reported success with albino skin using 2×10<sup>-4</sup> M DDC.

Triton treatment did not further stimulate the activity probably because freeze—thawing had already disrupted melanosomal membranes<sup>11</sup>. We were, however, also unable to confirm with skin, Hearing's observation<sup>3</sup> that albino eye homogenates are stimulated by Triton to a level equal to that of pigmented eye.

A distinct dopa oxidase is present in albino mouse skin. The tyrosine hydroxylation fraction still retains some dopa oxidase activity, but the presence of a dopa oxidase inhibitor in that fraction complicates the picture. It is uncertain how these findings relate to human albinism. Hair bulbs from one type of human albino<sup>12</sup> develop slight pigmentation when they are incubated for long periods with tyrosine.

Inhibitors of tyrosinase have been reported in albino eye<sup>3</sup> and many other tissues<sup>13</sup>. Their physiological role, however, remains obscure.

This research was supported in part by a grant from the National Cancer Institute.

#### Monosynaptic excitation of motoneurones from secondary endings of muscle spindles

SINCE Lloyd's original work on the myotatic unit more than 30 yr ago<sup>1</sup>, it has been assumed that the monosynaptic excitation of motoneurones from receptor nerve fibres derives entirely from the Group Ia afferents, which terminate as primary endings in the muscle spindles. Group Ib afferents from tendon organs are thought to exert their inhibitory actions<sup>2</sup> over di- or trisynaptic pathways3, while Group II and III fibres, which include those from the secondary endings of muscle spindles, form part of the flexor reflex afferent (FRA) system4, the synaptic actions of which are thought also to be mediated polysynaptically5. Whereas the monosynaptic excitation of motoneurones by Group Ia fibres has been directly confirmed in terms of unitary synaptic potentials evoked by single, stretch excited primary endings6, knowledge of the synaptic actions of fibres innervating secondary endings is known only indirectly from electrical stimulation of Group II fibres and is not without controversy7.

Here, avoiding the use of electrical stimulation, we have investigated the synaptic actions exerted on thoracic motoneurones by afferent fibres from primary and secondary endings of intercostal muscle spindles excited by stretch. We show that contrary to all previous beliefs, monosynaptic excitation of motoneurones can derive from secondary as well as primary

Cats anaesthetised with sodium pentobarbitone, paralysed with gallamine triethiodide and artificially ventilated were prepared for intracellular recording from expiratory motoneurones of the thoracic spinal cord at T8 as previously described8. One or several intramuscular nerve filaments supplying the internal intercostal muscle of T8 were freed but left in continuity9. Afferent impulses recorded from them were used to trigger a signal averager thus extracting from the intracellularly recorded synaptic noise averaged synaptic potentials evoked by individual receptor nerve fibres6

All signals were recorded on magnetic tape, which enabled subsequent detailed analysis of the synaptic potentials evoked by a large number of afferent fibres using the method shown

a, Experimental set-up. b, Spike-triggered average responses in an expiratory motoneurone. Three different window' settings of the spike discriminator, using as triggers from above down, large, medium and small amplitude spikes. Upper two traces, averages of 8,192 sweeps; lowest trace, average of 16,384 sweeps. Conduction distance, 47 mm to the ventral horn. c, Averaged responses evoked in two different expiratory motoneurones by the same, single unit trigger spike, together with its action potential averaged from the surface of the dorsal root ganglion (lowest trace). This unit showed a low dynamic sensitivity and a very regular firing pattern. Upper trace, average of 1,024 sweeps; lower two traces, averages of 8,192 sweeps. Conduction distances: 29 mm to the ganglion and 43 mm to the ventral horn. Calculated conduction velocity of the afferent,  $38 \text{ ms}^{-1}$ . Calibrations, 5 ms and 10  $\mu$ V, except c, 1  $\mu$ V for lowest

schematically in Fig. 1a. The filament recording was fed to 'window' discriminator so that spikes of given amplitude range could be selected as triggers for the averager. Analysis wa carried out by repeated replaying of the tape, each time with different setting of the 'window', so as to obtain a sequence of records such as illustrated in Fig. 1b. Typically, the respons consisted of a composite synaptic potential which could b broken down into unitary synaptic potentials each defined by specific latency, having a fast rise-time (10-90% in 1.0 ms) and a maximum amplitude for a given setting of the 'window We interpret such a response as indicating that each filamen contains several receptor nerve fibres monosynapticall connected to the motoneurone concerned. This interpretation depends on the assumption that a polysynaptic pathwa would result in a synaptic potential with a much slower rise time in the averaged record because of variability in the firing times of the relevant interneurones10.

The individual latencies of the unitary synaptic potential together with an assumed value for the synaptic dela (0.5 ms) give the conduction velocities of the individual fibre concerned, and these have ranged from 24 ms -1 to 90 ms -

thus including the range given for afferent fibres from intercostal secondary as well as primary endings by Andersson, Lennerstrand and Thoden<sup>11</sup>. An error in the estimation of conduction velocity could arise, however, from slowing in the intraspinal, preterminal region of the afferent fibre 12. An independent measurement of conduction velocity was therefore obtained by recording on a separate tape channel the signal from the exposed surface of the dorsal root ganglion at T8, so that simultaneously averaged recordings were obtained of the action potentials in individual fibres at the ganglion and of the synaptic potentials they evoke (Fig. 1c). Control recordings made in a similar fashion distal to the ganglion showed that the ganglion recording gave reliable estimates of the peripheral conduction velocities. The resulting measurements gave conduction velocities which remained in agreement with both ranges of Andersson et al.11. Of 17 fibres giving monosynaptic excitation, seven had velocities above 60 ms<sup>-1</sup> and three between 60 and 40 ms<sup>-1</sup>; the remaining 6 had velocities below 40 ms<sup>-1</sup> and fell completely within the range for secondary endings given by Andersson et al. V. Individual fibres were shown to excite monosynaptically more than one motoneurone, as illustrated for the secondary ending of Fig. 1c.

All clearly distinguishable units in the filaments were sensitive to stretch and most fell into two classes. They displayed either a high dynamic sensitivity with a relatively irregular discharge or a relatively low dynamic sensitivity with a regular firing pattern, corresponding to reported properties of primary and secondary muscle spindle endings13,14. Both classes were represented among those afferents giving monosynaptic excitation. This further supports our conclusion that monosynaptic excitation of thoracic motoneurones derives from both primary and secondary muscle spindle endings.

These results have several important implications which here can be dealt with only briefly. First, motoneurones participating in the intercostal stretch reflex must draw monosynaptic excitation from secondary as well as primary endings. This stretch reflex, which has been demonstrated in cats under a variety of experimental conditions (including anaesthesia) and in conscious man, has been directly implicated in the servo -control of intercostal muscles<sup>15</sup>. Second, the relatively delayed excitation by secondary endings could provide an explanation for the long latency of the human intercostal stretch reflex, although such an explanation does not in itself -account for the absence of early servo correction by the Group a afferents<sup>16-18</sup>. Third, because of their monosynaptic connections, the secondaries, like the primaries, are favourably sited to undergo sprouting in the advent of degeneration of central nerve fibres also terminating directly on motoneurones. This postulated growth of stretch activated synapses could be the major factor in the increased resistance to stretch of spastic muscles.

Finally, we suggest that further application of these techsiques could provide direct evidence to support the hypothesis of Matthews 19,20 that secondary endings contribute excitation o the soleus stretch reflex of the decerebrate cat and thus to efute contrary evidence derived from electrical stimulation of

This work was supported by a grant from the National fund for Research into Crippling Diseases.

Note added in proof: We have now extended these experiments to the triceps surae muscle and find the same result, that learly identified afferents from secondary endings monoynaptically excite homonymous motoneurones. This contitutes the direct evidence which we postulated above would upport Matthews' hypothesis. Our experiments so far have →een on anaesthetised preparations.

#### Comparison of the number of anti-L-binding sites on LK goat red cells with the number of Na-K pumps

SHEEP<sup>1</sup>, goats<sup>2</sup>, possums<sup>3</sup> and some other species are unusual mammals in that the red cells of individual animals have either high (HK) or low (LK) concentrations of potassium, which correlate with the activity of the Na-K pump. The pump of LK cells is less active than that of HK cells4.5. When LK sheep red cells are injected into HK sheep an antibody of the IgG class (anti-L) is raised which, when reacted with LK sheep or goat red cells, stimulates the pump<sup>5,6</sup>. In goat cells the major, if not the only, effect of the antibody is to reduce the affinity of the pump for K at the inside cell surface, and that stimulation results from the relative increase in the effectiveness of Na as a substrate. It has been reported that in sheep, anti-L also increases the maximal pump rate<sup>8</sup>. The antibody might function by binding either to the pump, and so altering its kinetic characteristics, or to another component of the cell surface, indirectly altering the environment of the pump. If it combines with the pump, the number of anti-L molecules bound should be about the same as the number of pumps. We have now confirmed this using an estimate of the number of pumps of LK goat cells obtained with <sup>3</sup>H-ouabain<sup>9</sup>, and our own estimate of the number of <sup>131</sup>I-labelled antibody molecules bound when the pump is stimulated maximally. We used LK goat red cells as LK sheep red cells seem to contain a second antigen in addition to the antigen associated with pump stimulation5,10.

The antiserum used in these experiments was obtained from one HK sheep after immunisation with cells from a single LK sheep. No haemolysing antibodies for the red cells of the HK and LK goats used in this study were present in the serum. The antiserum was absorbed against cells from three HK sheep. The methods used for determining the number of antibody-binding sites were similar to those used in determining the number of anti-D binding sites on human red cells<sup>11</sup>. IgG was purified by

Table 1	Binding of anti-L by HK and LK goat red cells					
Antibody quantity (mg)	Molecules bound HK LK-1 LK-2				nal pump ulation LK-2	
$\begin{array}{c} 2.2  \times  10^{-3} \\ 0.7  \times  10^{-3} \end{array}$	8	41 17	42 16	1.83 1.12	1.96 1.24 .	

HK and LK goat red cells were exposed to purified antibody at 32° C for 0.5 h, the cells were separated from the antibody by centrifugation and washed in the cold, and then separated into two parts one of which was used for the determination of the number of <sup>131</sup>-labelled molecules bound and the other for the determination of the ouabain sensitive K influx in quadruplicate. It was determined that maximal stimulation was established during a 0.5-h incubation of LK cells with anti-L, and that none of the antibody was eluted from the cells during a 1-h incubation at 0° C (as judged by the pump-stimulating effect of the antibody). Fractional pump stimulation was calculated as the pump rate in the antibody-treated cells divided by the pump rate in control cells. Similar results were obtained at five other antibody concentrations.

ammonium sulphate precipitation and repeated chromatography on DEAE cellulose; immunoelectrophoresis against anti-sheep serum revealed a single band. The IgG was iodinated by the iodine monochloride method<sup>12</sup>; protein labelled with <sup>131</sup>I was diluted with IgG labelled with nonradioactive I. Labelled anti-L was absorbed on cells from one of the LK goats in the presence of a large excess of unlabelled nonimmune sheep IgG. The cells were washed and haemolysed, and the antibody was eluted from the ghosts with butanol13, the purified antibody was diluted with a large excess of unlabelled nonimmune sheep IgG and dialysed against phosphate-buffered saline. LK and HK goat cells were exposed to the purified antibody for 0.5 h at 32° C, washed, and part of the cells was then used to determine the number of 131I-labelled anti-L molecules bound and another part was used for the determination of the ouabain-sensitive K influx7. Solutions used during exposure of the cells to antibody and measurement of K influx have been described7.

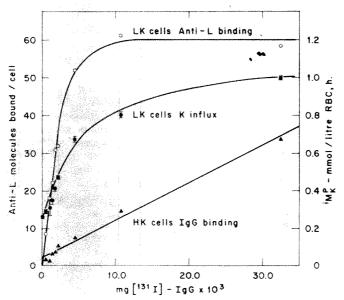

Fig. 1 The number of <sup>131</sup>I-IgG molecules bound to HK goat red cells ( $\triangle$ ) and the number of anti-L molecules bound to LK goat red cells ( $\bigcirc$ ) (calculated as the total number of <sup>131</sup>I-IgG molecules bound to the LK cells less the number bound to HK cells at the same antibody concentration) plotted against the number of mg of labelled IgG to which the cells were exposed (the total volume of solution containing the antibody was 5 ml for all points except the last, for which it was 7.5 ml). The simultaneously determined ouabain-sensitive K influx ( ${}^tM_K{}^p$ ) in the LK cells is also plotted ( $\bigcirc$ , right abscissa,  $\bot$  s.e.m., n=4) as a function of the amount of antibody to which the cells were exposed. Exposure of these cells to anti-L IgG labelled with nonradioactive I at a ratio of 1 ml of cells to 5 ml IgG (80 mg protein ml<sup>-1</sup>) resulted in a pump rate of 0.885  $\bot$  0.011 mmol per 1 red blood cells per h. The curves were drawn by eye; the HK line is a least squares plot, r=0.994.

At equal concentrations of labelled antibody, cells from the two LK animals took up about the same amount of antibody (Table 1). The number of labelled molecules taken up per cell by the HK cells was a significant percentage of the number taken up by the LK cells; this uptake was thought to represent nonspecific absorption of labelled antibody14. Since the total number of antigen sites is so low on LK cells, the elution process (which presumably removes both specifically bound and nonspecifically bound IgG) does not result in a monospecific antibody preparation. In calculating the number of anti-L molecules bound to LK cells, the number of molecules bound to HK cells at each antibody concentration was subtracted from the total number bound to LK cells. Since the number of anti-L molecules bound to the LK cells from each animal is about the same it is unlikely that there are any antibodies present to antigens other than that associated with pump stimulation.

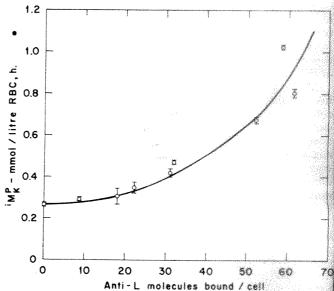

Fig. 2 The ouabain-sensitive K influx in LK cells  $(M_k^p)$  is plotted as a function of the number of anti-L molecules bound per cell; the data are from Fig. 1.

In Fig. 1 the number of antibody molecules bound to His cells and the number of corrected anti-L molecules bound to Lis cells is plotted as a function of the amount of labelled antibod to which the cells were exposed. The pump rate determined of the same LK cells is also plotted as a function of the amount of antibody. The number of molecules bound to HK cells is linear function of antibody concentration (as would be expected if this represents nonspecific binding), but the number of antimolecules bound to LK cells saturates at about 60 per cell which is close to the number (55) of pumps calculated from <sup>a</sup>H-ouabatic binding to the same cells<sup>a</sup>. As the number of anti-L inolecule bound approaches saturation, the stimulated pump rate als approaches saturation. It was not possible to determine the equilibrium constant for the antigen—antibody reaction since the eluted antibody contained large amounts of non-anti-L IgG.

In Fig. 2 the pump rate is plotted as a function of the number of antibody molecules bound. The stimulation of the pump rate is not a linear function of the number of antibody molecule bound; rather, the pump rate increases more rapidly at his antibody concentrations (high number of molecules bound than at low. This may reflect heterogeneity in the population of LK pumps so that the pumps with higher affinities for antibod are less stimulated than are those with lower affinities or it may indicate that more than one anti-L molecule per pump must be bound before the pump is stimulated. Since similar heterogeneity has been observed in the affinity of LK pumps for ouabain, the former possibility seems more likely.

Since the number of anti-L molecules bound to LK goat cel when the pump is maximally stimulated by anti-L (about 60) the same as the number of 3H-ouabain molecules bound by the same cells at 100% inhibition of the pump (about 55), it is concluded that anti-L combines with the pump (or with an antigen present in the same amount as the pump). Alteration of the kinetic characteristics of LK pumps by anti-L probably results from a conformational change induced in the pump by its combination with the antibody.

#### Reaction of human smooth nuscle antibodies with human blood ymphocytes and lymphoid cell lines

ANTIBODIES to smooth muscle appear in serum from cases of ctive chronic hepatitis1,2 and transiently in various acute viral iseases3,4. The smooth muscle antibodies (SMA) are demontrated by indirect immunofluorescence (IFL) using cryostat ections of rat stomach and kidney and human thyroid5. The eaction of SMA-positive sera with lymphoid tissue has been ointed out6.7. Here we deal with the reaction of SMA in idirect IFL on human peripheral lymphocytes and especially with lymphoblastoid cell lines.

Lymphocytes were purified from defibrinated blood by gelatin edimentation. Phagocytic cells were removed with iron powder nd erythrocytes lysed by 0.83% NH<sub>4</sub>Cl solution. After washing a saline the lymphocytes were cultured with or without the ddition of phytohaemagglutinin (PHA) (Burroughs Wellcome), .5 μg per 106 cells ml-1, in RPMI-1640 medium enriched with 0% human AB serum. After 18 h culture, the medium conaining PHA was removed and new medium was added. Cell reparations were made at varying intervals as is shown in Table

After three washes in saline, the cells from each tube were suspended in 0.05 ml of 0.034 M sodium citrate, smeared, ried and fixed in dry acetone at -20° C. Preparations from our different donors were examined by IFL.

Cells from lymphoid cell lines were grown in suspension alture in RPMI-1640 medium supplemented with 15% foetal

calf serum. Two lines of Epstein-Barr virus (EBV) transformed lymphocytes, Robinson-7481 and Moore-7002, and one leukaemia cell line MOLT-4 (ref. 8), were tested. After three washes, cell smears were prepared in sodium citrate as described above. Cell preparations from nonlymphoid cell lines of human (HeLa cells) and mouse origin (L cells) were prepared in a similar manner. SMA-positive sera were allowed to react with the cell preparations using indirect IFL. The anti-human Igconjugate and the optic system used have been described earlier6.

Ten different SMA-positive sera were tested on lymphoblastoid cell lines and all gave the same type of reaction. Only the reactions of one representative serum 2888/73, will be reported here. This serum has been described earlier<sup>6</sup>. All SMA reactions of this serum were removed by absorption with an extract of smooth muscle from pig stomach5. Extracts for absorption were also made from lymphoblastoid cell lines, HeLa and L cells. One part of packed cells was mixed with two parts of phosphate-buffered saline and homogenised in an Omnimixer for 8 min. The supernatant obtained after centrifugation at 3,000 r.p.m. for 15 min was used as antigen for absorption. The

antiserum 2888/73 was absorbed twice with equal volumes of the different cell extracts (Table 2).

A prerequisite for the demonstration of the microvilli of lymphoid cells was that the cells were suspended in 0.034 M sodium citrate before the preparations were made or that chelating agents were added.

SMA-positive serum showed by IFL a cytoplasmic or a membrane type reaction with lymphoblastoid cells. The most conspicuous finding was, however, the strongly fluorescent long 'hairy' microvilli extending from the surface of single cells (Fig. 1a and b), usually asymmetrically concentrated to one side of the cell. Most cells with long fluorescent microvilli showed very little cytoplasmic staining. The microvilli could reach the length of the diameter of the cell but they were usually shorter or around 1/3 of the diameter. The appearance of the surface microvilli seemed to vary somewhat with the cell cycle and with the growth conditions of the cells (Table 1). MOLT-4 cells had in comparison with cells belonging to the Moore or Robinson lines only short stub-like villi and fewer cells were positive (Table 1). Myeloma cells from an IgE producing line (obtained from Dr Kenneth Nilsson, Uppsala) showed no reaction with SMA.

Wet preparations of living lymphoblastoid cells were examined by phase contrast microscopy. Almost all cells had microvilli. Attempts to stain live suspended cells with SMA-positive serum by IFL were, however, negative.

Smeared and acetone fixed HeLa cells and L cells showed no microvilli stained with SMA-positive serum but a moderate or weak reaction of the peripheral part of the cytoplasm or of the membrane especially when the cells were in aggregates. This was considered to be a kind of contact phenomenon.

Absorption of serum 2888/73 with SM antigen from pig stomach removed all IFL staining of lymphoblastoid cells and also the SMA pattern on the tissue sections. The outcome of the absorption experiments is shown in Table 2. Extracts of Moore cells were almost as effective as extracts of the muscle layer of pig stomach. Extracts of HeLa cells and L cells hardly changed the titre of serum 2888.

When SMA-positive sera were set to react in IFL with smears of peripheral lymphocytes from normal blood donors a moderate reaction was observed with the cytoplasm or the membrane of 60-80% of the cells. About 5% of the cells had short villi (Table 1). When cells had been cultured for 3 h in a medium containing PHA, the cells in the aggregates formed were strongly positive (Fig. 1c). Cells cultured without PHA showed a weaker membrane-like staining (Fig. 1d) best visible when the cells were in close contact. At 18 h the IFL staining of the aggregated cells, cultured in the presence of PHA, was stronger than after 3 h. At 42 and 66 h many of the aggregates had broken up and many large and small cells with short microvilli could be seen (Table 1). Occasionally cells with long and asymmetric villi were observed resembling the lymphoblastoid cells described above. A similar increase in villi-containing cells has been observed in transmission EM after PHA stimulation11

'Hairy' cells have been observed earlier by phase contrast using wet preparations of cultured lymphoid cells, possibly pure B cell lines9. By scanning electron microscopy (SEM) lymphoid B

cells were shown to have long villi whereas T cells (MOLT-4 had small stub-like projections<sup>10</sup>. In the present investigation by IFL, the T cell line MOLT-4 and the probable B cell lines Moon and Robinson also showed differences in morphology, the lattel cells having more and longer villi staining with SMA-positive serum than had the MOLT-4 cells.

We have demonstrated that the SM antigen present in the peripheral lymphocytes increases considerably when the cellare stimulated by PHA. Surface microvilli appear stainable by SMA-positive serum. Such surface microvilli are present in high amounts in EBV-transformed lymphoblastoid cells. We sugges that the demonstrated SM antigen, probably consisting of contractile protein(s)12, in the microvilli are of biologica importance for the lymphoid cells, for example, in their mobility The cell lines Robinson-7481 and Moore-7002 were provide by Dr George E. Moore, Buffalo. This work was supported b the Swedish Cancer Society. K.L. received a grant from Ander Otto Swärds foundation.

#### Replication of oncornavirus-like particle in human breast carcinoma cell line, MCF-7

THE search for RNA-containing human breast cancer virus has been helped by the discovery of several biochemical an biophysical characteristics of the oncornavirus group<sup>1</sup> Although these properties may not be unique to oncorn viruses<sup>5</sup>, they provide biological reagents for more discrimina ing tests<sup>6-8</sup> to establish species of origin, natural history ar virus taxonomy for candidate viruses exhibiting these pro-

Oncornavirus-like particles have been detected in human milk<sup>1-4</sup> and in breast carcinomas<sup>8,9</sup>. Evidence for oncornavirus infection in cultures of normal breast cells10, and breast carcinoma cells<sup>11</sup> has also been reported. To date, however, undefined cultural exigencies have precluded the general usefulness of established mammary carcinoma cell lines for growing particles to levels sufficient for characterisation as human breast cancer viruses. It should be noted that replication of the mouse mammary tumour virus is, in many cases, also severely restricted in monolayer cultures of mouse mammary tumour cells 12,13. This restriction can be largely prevented by cultivating mouse mammary tumour cells in conditions permissive for the expression of normal mammary cell differentiative functions<sup>12</sup>.

To obtain optimum culture conditions for the replication of putative human breast oncornavirus, MCF-7 human breast arcinoma cells were cultivated so as to maintain several activities of differentiated mammary epithelial cells. The presence of specific 17β oestradiol receptors and synthesis of & actalbumin (W. W. Rose and C. M. McG., unpublished) uggest the expression of differentiative features of mammary pithelium by MCF-7. MCF-7 is an established subtetraploid ell line originally derived from a pleural effusion of a female atient with malignant adenocarcinoma of the breast14. several criteria were used to establish the human nature of the cells<sup>14</sup>. These cells are free of mycoplasma<sup>14</sup>. Here we describe he isolation of an oncornavirus-like particle from MCF-7 cells and the results of immunofluorescence studies to characterise he particle serologically.

The density distribution of RNA-containing particles released rom MCF-7 cells during a 48 h 3H-uridine labelling period at 5°C is shown in Fig. 1a. The buoyant density of the major earticle population was determined to be 1.17 g ml<sup>-1</sup> ( $\pm 0.01$ ) in reformed sucrose gradients. A second, minor population, with density of 1.23-1.25 g ml<sup>-1</sup>, was also detected in some experiments. These particles, which represented 1-20% of the total a.p.m. in gradients, have yet to be fully characterised. When ells were labelled at 37° C instead of 25° C, however, only articles with densities of 1.23-1.25 g ml<sup>-1</sup> were recovered.

From the 1.16-1.18 g ml<sup>-1</sup> region of 15-65% sucrose gradients fifty different experiments  $5 \times 10^3 - 10 \times 10^3$  d.p.m. were ecovered. This corresponds to a yield of  $5 \times 10^3 - 10 \times 10^3$ p.m.  $734B/25 \times 10^6$  cells per 48 h in our labelling and purificaon conditions (Fig. 1a).

RNA was extracted from <sup>8</sup>H-uridine-labelled, isopycnicallyanded particles and was sized by gel electrophoresis. Four NA populations were identified in the 734B ( $\rho = 1.16-1.18$ ) article population (Fig. 1b). The major RNA species had a colecular weight of  $10 \times 10^6$ – $12 \times 10^6$ . The molecular weight of second heterogeneous population of RNA was  $\sim 3 \times 10^6$ - $\times$  10°. A third (high molecular weight) population ( $\sim 1 \times 10^6$ –  $2\times10^6$ ) coelectrophoresed with 28S (molecular weight  $1.75\times$ 106) ribosomal RNA from MCF-7 cells and probably reflected microsomal contamination in the gradient. The fourth population was heterogeneous low molecular weight RNA. Parallel sedimentation velocity analyses of 734B RNA also resolved four populations, 62-70S, 35-38S, 26-28S and 4-10S, which correspond well with molecular weight estimates of 734B RNA in sizing gels.

Particles isopycnically banded as above, were assayed for reverse transcriptase activity using endogenous RNA as template. The products of a 1 h 37° C reaction are shown in Fig. 2. The major RNA species consistently served as template for the polymerase reaction. Recovery of a discrete product (molecular weight  $3 \times 10^6 - 5 \times 10^6$ ) was variable but products

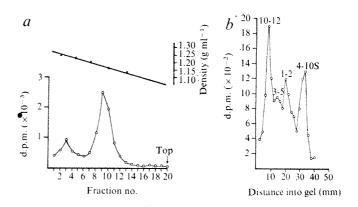

Fig. 1 a, Buoyant density of 734B particles in sucrose. Immediately before labelling  $25 \times 10^6$  MCF-7 cells with <sup>3</sup>H-uridine (15  $\mu$ Ci ml<sup>-1</sup>, New England Nuclear, specific activity = 20 Ci mol<sup>-1</sup>), growth medium (Eagle's MEM+10% calf serum (Flow Laboratories) + 10  $\mu$ g ml<sup>-1</sup> insulin) was replaced with MEM+5% heat inactivated (56°/30 min) calf serum+10  $\mu$ g ml<sup>-1</sup> insulin, and the incubation temperature lowered to 25°-29° C. After a 48 h label, particles were partially purified by a series of centrifugations in discontinuous and linear sucrose gradients<sup>13</sup> prepared in TNE buffer (0.01 M Tris-HCl, 0.15 M NaCl, 0.001 M EDTA, (pH 7.4)). Trichloroacetic acid precipitable <sup>3</sup>H-uridine d.p.m. in 0.2 ml fractions from linear 15-65% sucrose gradients after a  $14.1 \times 10^{6}g$  minimum centrifugation of particles to equilibrium is shown. Radioactive materials were counted using a Beckman model 3380 instrument calibrated to deliver absolute activity (d.p.m., which corresponds to 4-5×c.p.m. values). b, RNA extracted from 734B particles. Labelled particles released from  $75 \times 10^6$  cells were isopycnically banded as in Fig. 1. The 1.16-1.18 g ml<sup>-1</sup> region was pooled and pelleted in TNE buffer. RNA was extracted with sodium dodecyl sulphate (SDS) (0.75% final concentration) and phenol as described previously<sup>13</sup>. RNA was sized in 7.0 cm, 1.8% acrylamide/0.5% agarose composition gels<sup>25</sup> and mouse 28S (molecular weight 1.67×10°) cell RNA was used as an external marker. Each fraction represents 2 mm gel slices. Numbers over radioactive peaks represent apparent molecular weights in millions of daltons derived from the external marker.

Table 1 Reactivity of MCF-7 cells with anti-MuMTV and anti-MuLV sera in immunofluorescence tests

Market Control of the						
		I	Reactivity (% Cel	lls fluorescing)	1	
ntiserum	MCF-6	BALB/c cl-5	BALB/cfc3H	MCF-7w	MCF-7 cl-1	D-562
3AV*	0	0	40-75	5-7	0	0
3AV absorbed with MuLV†	0	0	4075	5-7	0	0
3AV absorbed with BALB/c cell1	0	ND	40-75	57	0	0
3AV absorbed with MuMTV§	0	ND	0.1 - 1.0	0	0	0
ormal rabbit serum	0	0	0	0	0	0
nti-MuLV	100	0	0	0	0	0

<sup>\*113</sup>AV was prepared in rabbits against MuMTV isopycnically banded from BALB/cfC3H milk. The serum was absorbed twice with BALB/c ilk, then absorbed overnight in female BALB/c mice before use. A 1:4 dilution of serum was used in each indirect immunofluorescence test<sup>24</sup> †MuLV grown in BALB/c spleen cells (MCF-6).

BALB/c cell is a lyophilised preparation of homogenised BALB/c mammary glands.

SMuMTV for absorption was isopycnically banded from BALB/cfC3H milk. Three absorptions were required to reduce reactivity of the rum from BALB/cfC3H cells to 0.1-1.0%

Anti-MuLV was obtained from Flow Laboratories and contained both anti-gs-1 and anti-gs-3 reactivity20. The serum was used at a 1:100

Cells used: MCF-6, a leukaemic BALB/c spleen cell line<sup>19</sup>; BALB/c, a cloned derivative of a BALB/c mammary tumour cell line<sup>27</sup>; BALB/C3H, Primary cultures of BALB/cfC3H mammary tumour cells<sup>13</sup>; MCF-7w, uncloned cultures of MCF-7 cells<sup>14</sup>; MCF-7 cl-1, a cloned subline MCF-7; D-562, a human cell line derived from a pleural effusion of a patient with a throat adenocarcinoma18.

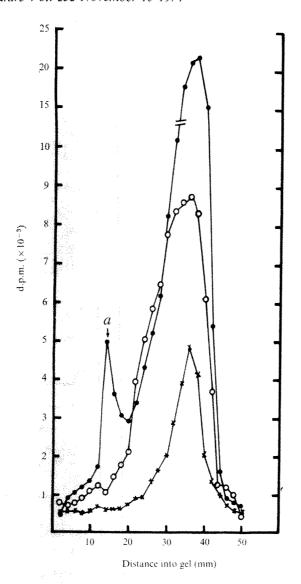

Fig. 2 Endogenous reverse transcriptase activity of 734B particles. Unlabelled particles released from 100 × 106 cells were isopycnically banded as for Fig. 1. The 1.16–1.18 g ml<sup>-1</sup> region was pooled and pelleted through a cushion of 15% sucrose in TNM buffer, pH 7.4 (Tris-HCl [0.01 M], NaCl [0.15 M], MgCl<sub>2</sub> [0.003 M]). Reverse transcriptase assays were performed<sup>1</sup>. The incubation mixture consisted of 734B protein (130 μg), NP-40 (0.2%), DTT (0.033%), KCl (0.04 M), MgCl<sub>2</sub> (0.006 M), dATP, dGTP, dCTP (0.8 μmol ml<sup>-1</sup> for each) and <sup>3</sup>H-TTP (100 μCi, specific activity = 40 Ci mmol<sup>-1</sup>). Reactions at 37° C were terminated after 1 h by addition of NaCl (to 0.4 M), SDS (to 1%) and phenol (to 50%). Phenol extracted products were sized in 1.8% acrylamide/0.5% agarose gels<sup>25</sup> and the molecular weight of products was determined from the position of an external 1.67 × 106 molecular weight marker (ribosomal 28S RNA). The major product (molecular weight 10 × 106–12 × 106) corresponds to the radioactivity in the peak under a. • Products from a 1 h standard reaction<sup>1</sup>; ○, products from a 1 h reaction incubated with pancreatic RNase (10 μg ml<sup>-1</sup>) for 15 min at 37° C before addition of nucleoside triphosphates; ×, products from a 1 h reaction in which deoxyguanosine triphosphate had been omitted from the reaction mixture. 734B protein (43 μg) was included in all three reactions.

ranging in size from  $4 \times 10^6$  to small (4S) fragments were routinely recovered in a single heterogeneous peak which, when integrated, accounted for the vast majority of  $^3$ H-TPP c.p.m. after 1 h enzyme reaction.

Preincubation of the NP-40-disrupted 734B with pancreatic ribonuclease (10  $\mu$ g ml<sup>-1</sup> at 37°C) virtually eliminated the <sup>3</sup>H-TTP counts in the  $10\times10^6$ – $12\times10^6$  molecular weight region of sizing gels (Fig. 2) indicating that the high molecular weight RNA served either as template or primer in the reaction. The

lower molecular weight products were reduced by approximately 65%. Omission of deoxyguanosine triphosphate from the reaction mix also eliminated the  $^{8}$ H-TTP c.p.m. from the  $10 \times 10^{6}$ - $12 \times 10^{6}$  molecular weight region of the ge (Fig. 2), and reduced the smaller molecular weight produce by approximately 85%. This indicates synthesis of a propenter opportunity of high molecular weight RNA-DNA rather than terminal addition of  $^{8}$ H-TTP to RNA by a terminal transferase.

Analysis of the reaction products in CsSO<sub>4</sub> gradients ind cated that 15–30% of the total product after 1 h incubatio consisted of RNA-DNA hybrids with a density range (1.68–1.55 g ml<sup>-1</sup> (Fig. 3). The remainder consisted of DN (density ~1.45, Fig. 3). That the RNA-DNA product was hydrogen bonded heteroduplex rather than a covalently linke polynucleotide was shown by denaturing the product if formamide<sup>17</sup> before analysis in CsSO<sub>4</sub> gradients (Fig. 3). Suc treatment resulted in removal of the <sup>3</sup>H-TTP counts from the RNA and hybrid regions of the gradient and recovery of the counts in the DNA region of the gradient (Fig. 3).

An antiserum against murine mammary tumour viru (MuMTV) (prepared against isopycnically banded virus from BALB/cfC3H mouse milk) reacted in indirect immunofluores cence tests with 5-7% of MCF-7 cells (Table 1). Granula fluorescence was primarily localised in the cytoplasm of staine cells. A cloned derivative of the human cell line which ha exhibited no evidence of 734B particle release (MCF-7 CIwith no reverse transcriptase activity in a 1.16-1.18 g ml gradient band) showed no reactivity with the anti-MuMT serum (Table 1). Similarly, another human epithelial cell lin (D-562), also derived from a pleural effusion<sup>18</sup>, and not asso ciated with particle synthesis, showed no reactivity with the anti-MuMTV serum (Table 1). The antiserum did not reac with BALB/c mouse cells infected with murine leukaemi viruses (MuLV) nor with MuMTV-free BALB/c mouse man mary epithelial cells27 (Table 1).

Absorption of this antiserum with either MuMTV-fre BALB/c mouse milk, MuLV grown in BALB/c cells or extract of BALB/c mammary glands had no effect on its reactivity with either MuMTV positive mouse cells in primary culture (BALB/cfC3H) nor with human MCF-7 cells (Table 1). It contrast, absorption with MuMTV isopycnically banded from

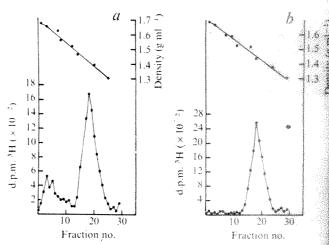

Fig. 3 Density of reverse transcriptase products in CsSO<sub>4</sub> gradients. Ethanol precipitated, SDS-phenol extracted product of a 1 h reverse transcriptase reaction (compare legend for Fig. 2) was further purified by the CTAB method<sup>28</sup>. The product reconstituted in  $0.5 \times SSC$  buffer and 50% formamide<sup>15</sup> (final concentrations), was divided into two equal aliquots. One half was heated at  $80^{\circ}$  C for 10 min, conditions adequate to melt RNA-DNA hybrid polymers<sup>17</sup>. Both heated and unheated products were dialysed against 0.001 M Tris buffer pH 7.0, mixed with CsSO<sub>4</sub> (p=1.51) and centrifuged 60 h at 45 K in a 50 Trotor at 25° C. a, Unheated product; b, product heated at  $80^{\circ}$  C

mouse milk resulted in a marked reduction of its reactivity with both BALB/cfC3H mouse cells and with MCF-7 cells (Table 1).

An antiserum against MuLV protein, reactive against both inter- and intraspecies MuLV group determinants 20, which in immunofluorescence tests was reactive to a dilution of 1:2,000 for MuLV positive mouse cells, was unreactive with MCF-7 cells even at a dilution of 1:100 (Table 1).

Thus, 734B particles, with a buoyant density of 1.16-1.18 g ml-1, a high molecular weight RNA and a bona fide reverse transcriptase enzyme seem to be antigenically unrelated to MuLV. This is consistent with results of biological tests in which concentrates of 734B particles and disrupted MCF-7 cells failed to induce leukaemia (or any other overt disease) in BALB/c mice. Similarly, 734B particles did not activate defective sarcoma virus in S+L- NIH Swiss 3T3 (ref. 22) cells.

The interpretation of the antigenic relationship between 734B and MuMTV is less clear. Studies of Black and his colleagues23 have suggested immunological cross reactivity between MuMTV and an agent in human breast carcinoma cells. Likewise, Axel et al.8 have suggested homology between MuMTV RNA and RNA from oncornavirus-like particles in human breast tumours. In our own studies, reactivity of 734B-synthesising MCF-7 cells with an anti-MuMTV serum (Table 1) coupled with the fact that the reactivity for MCF-7 cells could be absorbed from anti-MuMTV sera with purified 734B (C. M. McG., P. M. G., H. D. S., T. G., and M. A. R., unpublished), suggests an antigenic relatedness between MuMTV and 734B. Preliminary results of radioimmunoassays and protein sizing studies, however, suggest significant structural differences between MuMTV and 734B. Studies currently in progress in our laboratory to identify the protein(s) of 734B reacting with anti-MuMTV sera and to evaluate the homology between the RNAs from the two agents are aimed at the ducidation of their true relationship.

Definitive morphological characterisation of 734B requires nore particles than are synthesised in existing cultural condiions. We are now attempting to stimulate 734B particle production to reproducibly quantifiable levels by altering those conditions.

We are also actively engaged in experiments to establish species of origin for 734B as well as the natural history of 734B expression in normal breast and breast carcinoma cells using he DNA product of the reverse transcriptase reaction as a probe'6,21 for 734B information. This data is of obvious undamental importance for an understanding of the relationhip of 734B to human breast cancer.

We thank Abdon Long and Anne de Sostoa for technical ssistance. We also thank Dr J. Justin McCormick and Ms enora Larson for performing the reverse transcriptase assays nd for helpful discussions. This work was supported in part y an institutional grant to the Michigan Cancer Foundation rom the United Foundation of Detroit, Michigan and a grant rom the National Cancer Institute.

#### Unique increase of serum proteins and action of antitumour polysaccharides

WE have reported that lentinan and several other polysaccharides inhibited the growth of sarcoma-180 transplanted subcutaneously in mice1-4, and that their antitumour activity is a host-mediated reaction with participation of the thymus or thymus-dependent cells (T cells)5-8. While it has recently been reported that lentinan is a T cell oriented adjuvant9 and a helper T cell stimulant10-11, it is not clear how lentinan affects the host at the first stage before the induction of many immunological changes. It is possible that the antitumour activity of lentinan is dependent on the presence of certain substances in the host which interact with these polysaccharides.

We have found that three kinds of protein components, which are different from properdin, increase markedly in mouse serum soon after lentinan administration. It should also be noted that there is a close relationship between the increase of protein components and the antitumour activity of polysaccharides.

ICR female mice (body weight 20-25 g) were given a daily intraperitoneal injection of 4 mg per kg lentinan (the optimal dose for tumour regression) for 5 d. Serum was obtained conventionally from blood on days 1, 4, 7, 10, 14, and 21 after the final injection of lentinan. A 5 µl aliquot of serum obtained on each of these days was applied to polyacrylamide gel electrophoresis on gradient gel PAA 4/30 (Pharmacia Fine Chemicals, Uppsala) at 125 V for 15 h using 5 mM Tris-glycine buffer (pH 8.6). The gel was stained with 1% solution of Amidoblack 10B, followed by destaining in 7% solution of acetic acid.

The results of electrophoresis show that mouse serum proteins were divided into 21 fractions (Fig. 1). It is apparent that three protein components (LA, LB, and LC) markedly increase in

The mice were ICR female mice.

Date of peak was counted after the last injection of polysaccharides.

Carboxymethylpachymaran.

Molecular weight 200,000-275,000.

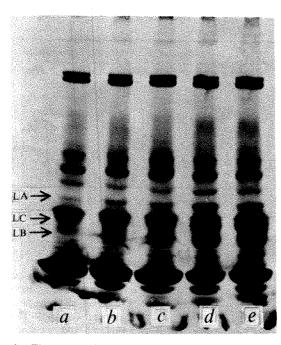

Fig. 1 The acrylamide gel pattern of serum samples from lentinan-treated mice. a, Control (fourth day after saline injection); b, first day; c, third day; d, fourth day; e, seventh day after the last injection of lentinan.

the serum of mice administered lentinan. Their increase peaked on days 4 to 7 after the final injection of lentinan, then gradually decreased, and the contents of LA, LB, and LC on day 21 were not different from those in control mice. Quantitative measurement of serum proteins with a densitometer showed that serum proteins LA, LB and LC on the fourth day after the last lentinan injection were 2.8, 2.4, and 2.1 times as much as those in the control serum. The ratio of LA, LB, and LC content to the whole serum contents was 6.2%, 10.3%, and 11.3%, respectively. Although the complete assignment of serum components fractionated by this method is not yet established. we consider that LA is  $\beta$  globin and LB and LC are  $\alpha$  globins.

Further, we studied the correlation between the increase of serum protein components and the antitumour activity of polysaccharides. The alteration in the content of serum proteins LA, LB and LC in mice administered polysaccharides with or without the activity was compared, the method being identical to that used with lentinan. These results are summarised in Table 1. There was an increase of serum protein LA, LB, and LC in mice administered antitumour polysaccharides, such as lentinan or pachymaran, even though the duration of peak varied. On the other hand, changes of serum protein LA, LB, and LC in mice given polysaccharides without antitumour

activity was not significantly different from those in control mice, except for pachyman.

Pillemer et al., reported that properdin, a B globulin, which was adsorbed from serum by incubation with zymosan, increased in titre 200-300% above the normal level 2-14 d after the intravenous injection of zymosan12-14. Serum protein LA, LB, and LC, however, were not adsorbed with zymosan or lentinan by Pillemer's method. In addition, there is much more LA, LB, and LC than properdin in serum. These findings seem to indicate that none of proteins LA, LB, and LC is properdin.

That the antitumour polysaccharides have an anticomplementary activity in vitro15, and that they affect a-helix content of serum albumin<sup>16</sup>, indicates that in an early stage, serum factors play an important role in tumour regression, as well as in cell-mediated immune responses. We consider that there may be a close relationship between the drastic increase of the proteins (LA, LB, and LC) and a potent stimulation of T helper cells<sup>11</sup>. Although the relation between these serum proteins (LA, LB, and LC) and the host defence mechanism against tumours remains obscure, the dramatic increase of these proteins by antitumour polysaccharides may indicate a new approach to the study of antitumour immunity.

#### Liposomes as immunological adjuvants

ADJUVANTS are widely used to increase antibody formation in experimental animals, for example, Freund's incomplete adjuvant, a water-in-oil emulsion containing the antigen, and Freund's complete adjuvant, which is the same but with killed tubercle bacilli. These adjuvants cannot be used in man because the mineral oil base is not degraded and persists at the injection site. Particularly with the complete adjuvant, unacceptable granulomas can be formed. There is real need for a safe and effective adjuvant for use in human immunisation programmes.

Such an adjuvant could reduce the amounts of antigens,

which is administered to humans, can be conveniently labelled with radioactive iodine and is readily incorporated into liposomes; the formation of antibodies can be measured easily by passive haemagglutination. Representative observations in mice immunised with free and liposome-entrapped DT by the intravenous and subcutaneous routes are presented in Table 1. DT administered intravenously in negatively-charged liposomes elicits the formation of much higher concentrations of antibodies than are elicited by free antigen. Subcutaneous (footpad) inoculation of DT in negatively-charged liposomes elicits significantly higher primary and secondary antibody responses than inoculations of the same doses of free antigen. In contrast, antigen entrapped in positively-charged liposomes elicits less antibody than the same dose of free antigen.

Intramuscular injection of DT in negatively-charged liposomes again elicits significantly higher antibody levels than free DT (Table 1). In these and other experiments, dicetylphosphate-containing liposomes as adjuvants were superior to those containing phosphatidic acid. When immune mice were inoculated intravenously with free DT they developed severe

Table 1 Serum antibody responses of mice to diphtheria toxoid administered free or in liposomes of different compositions

ĥ	6	-Liposomes (DP)	Intramuscular	6.6	12.0	f v h, P < 0.01

Mice were of the TO strain, except in groups c-e, which were of the CBA strain. Positive (+) liposomes (0.5 mg lipid) were composed of egg lecithin, cholesterol and stearylamine in molar ratios 7:2:1; in negative (-) liposomes phosphatidic acid (PA) or dicetylphosphate (DP) replaced stearylamine. Primary serum antibody responses were measured after 13 or 14 d, booster injections with 20 µg antigen in the same form were given and secondary responses were measured after a further 10 d (groups c-e) or 14 d (groups f-h). Antibody responses were measured by indirect haemagglutination (ref. 4) and expressed as the log<sub>2</sub> IH titre.

for example, diphtheria and tetanus toxoids, required for immunisation, with corresponding economies especially relevant to the developing countries. Live virus vaccines have hazards such as the potential initiation of persistent infections or malignancy, and vaccines containing killed viruses or viral antigens often require adjuvants to elicit the formation of protective antibodies. Another possible danger of the use of adjuvants is that in a minority of recipients they may induce allergic reactions to the vaccines which they contain, especially of antigens are administered twice to boost immunity, or if the recipients are already sensitised to an antigen at the time of its administration. It would be an advantage if the mode of presentation of antigens in the adjuvant were such as to avoid allergic reactions. If adjuvants consist of immunogenic materials such as glycolipids or proteins, even in trace amounts, they night themselves induce allergic or even autoallergic reactions through sharing of antigens with those of the recipient or some other mechanism.

We report here the use of liposomes, concentric spheres consisting of phospholipid bilayers separated by aqueous compartments, as immunological adjuvants. Protein and other antigens can be entrapped in liposomes, which have been proposed as carriers of therapeutic agents<sup>1,2</sup>, and we have ound that under certain conditions the administration of entigens so entrapped elicits the formation of more antibodies han are elicited by the same doses of free antigen. Liposomes an be made of non-immunogenic, biodegradable materials and their composition and properties such as electric charge an be varied at will. If animals which already have antibodies re challenged with antigens entrapped in liposomes they are nuch less likely to develop antibody-mediated allergic reactions han when challenged with the same doses of free antigens3.

Diphtheria toxoid (DT) was studied because it is an antigen

serum sickness reactions, and the majority died. In contrast, the same amount of antigen inoculated subcutaneously or intravenously did not elicit Arthus or serum sickness reactions<sup>3</sup>. The investigations which we have carried out show that liposomes are potentially useful as adjuvants and there is reason to believe that further modifications of the system, such as the incorporation of Bordetella pertussis, Mycobacterium tuberculosis or microbiological or chemical products known to have adjuvant activity, will further increase their usefulness in practice.

#### Differences in the effects of adult thymectomy on T-cell mediated responses in vitro

EVIDENCE exists indicating that functionally different subsets of T lymphocytes are activated during the in vitro allograft response. Thus, the T cells responding primarily by proliferation in the mixed lymphocyte culture (MLC) may be distinct from the T cells which differentiate to killer cells and display specific target cell lysis  $(CML)^{1-3}$ . The biological properties of the T-cell subsets involved are incompletely known. Adult thymectomy (ATX) in mice and rats alters certain T lymphocyte mediated functions. Spleen T cells forming rosettes with sheep erythrocytes disappear as soon as 5 d after ATX <sup>4.5</sup>. Lymphocyte with high amounts of surface  $\theta$  antigen are depleted from the spleen within a few weeks after the operation (Ref. 6 and C. Fournier and J. F. B., unpublished).

These early changes in the T-cell functions following ATX have been taken to indicate the existence of a newly formed, shortlived T lymphocyte population in the spleen regulated by the intact thymus either through a continuous cell traffic from the thymus or through the action of a thymic hormone? We have investigated whether the proliferating and lytic functions in the MLC-CML may be distinguished by selective depletion of a thymus-dependent (T) cell population by ATX, and also tested the effect of ATX on the *in vitro* responses of mouse spleen cells to the T mitogens, phytohaemagglutinin (PHA) and concanavalin A (con A). The results indicate that the killer cell precursors are more dependent on intact thymus function than the precursors of proliferating cells.

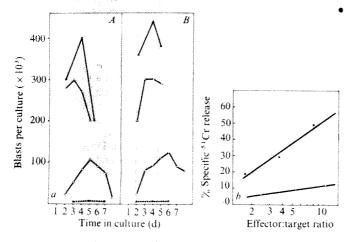

Fig. 1 a, Responses of CBA/H spleen lymphocytes to DBA/2 mitomycin-blocked spleen cells (○), PHA (△) and con A (■) 56 d after adult thymectomy. -•-•, background responses of non-stimulated CBA/H cells. A, lymphocytes of ATX mice; B, lymphocytes of STX controls. b, Lysis of P-815 mastocytoma cells by CBA/H + DBA/2m-primed cells on the day 7 of culture in the MLC. ○, MLC responder cells from ATX mice; ●, responder cells from STX controls (10,000 target cells, exposure time 6 h).

CBA/H-T6T6 or CBA/H mice were thymectomised by suction at 5 and 6 weeks of age. Age- and sex-matched controls were either sham-thymectomised (STX) or left untreated. Three separate experiments, each including 30-80 ATX mice were performed. Three to ninety days after the thymectomy the spleens were removed, spleen cells of three to five mice in each group were pooled and the lymphocyte-enriched population of the spleen cells (yielding approximately 85% of lymphocytes) was processed as described<sup>8</sup>. The spleen lymphocytes were then passed through nylon-wool columns9 to remove most of the non-T cells. After the procedure, 8-15% of the cells were found to carry surface immunoglobulin detectable by immunofluorescence with FITC-conjugated sheep anti-mouse Ig; 1.5 imes106 spleen lymphocytes from each group were cultured with optimal concentrations of PHA-M (Difco Pharmaceuticals, Detroit, final dilution 1.150) or con A (final dilution 10 µg<sup>-1</sup> ml) in 2ml of Eagle's minimal essential medium (Orion Pharmaceuticals, Helsinki), substituted with 5% of heat-inactivated foetal calf serum from selected batches (Flow Laboratories, Irvine, Scotland) in 11.5  $\times$  100 mm round bottom test tubes (Münnerstadt Glasswahrenfabrik, Münnerstadt) in a humidified atmosphere of 5% CO<sub>2</sub> in air<sup>8</sup>. Alternatively, the spleen lymphocytes were stimulated by 3.0 imes 106 mitomycin-C blocked DBA/2

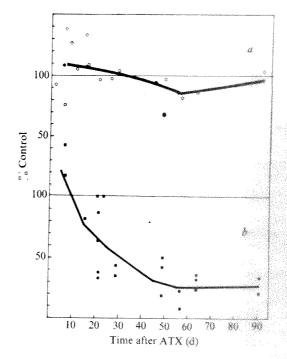

Fig. 2 Responses of CBA spleen lymphocytes to allogeneic lymphocytes (DBA/2m) in MLC (a) and lysis of P-815 (DBA/2) mastocytoma cells by MLC-primed cells (b), 3 - 90 d after adult thymectomy. All responses given as % responses of shamoperated control spleen cells tested on the same day. For detail see text.

cells (referred to in the text as DBA/2m) in conditions where only T cells are responsive<sup>10,11</sup>. On day 7 or 8 of culture, the MLC-primed cells were tested for the ability to lyse relevant <sup>51</sup>Cr-labelled P-815 mastocytoma target cells. In the cell-mediated lysis (CML) test<sup>8</sup> standardised conditions and 6 h exposure times were employed. Specific <sup>51</sup>Cr release was calculated according to Brunner<sup>12</sup>, the background release being in all experiments less than 15% of maximal release.

Examples of typical mitogen, MLC and CML responses by lymphocytes from thymectomised and sham-thymectomised mice in a single test (56 d after the thymectomy) are given in Fig. 1a and b. Fifty six days after ATX, the mitogen and MLC responses were close to sham-operated controls, whereas the CML response was clearly depressed. As responses of spleen lymphocytes obtained from non-treated control mice did not significantly deviate from sham-operated controls, the nontreated controls have not been included in the results. Figure 2 summarises the pooled data of the three separate experiments As regards the mitogen and MLC responses, only maximal responses, regardless whether they take place on the same day or not, have been considered. The responses of lymphocytes obtained from thymectomised mice are expressed as percentage responses of lymphocytes obtained from sham-operated controls. Spleen lymphocytes from ATX mice responded less efficiently to PHA from week 3 onwards after the thymectomy, The responses remained depressed for approximately 8 week but then returned back to control level. A similar depression taking place in approximately equal time period after ATX, was observed in the responses of spleen lymphocytes to con A. The depression, however, was not as remarkable as the depression of the response to PHA. A slight depression in the response of spleen lymphocytes to allogeneic cells was observed 7-9 week after adult thymectomy. This was in marked contrast with the effect of ATX on the CML response by MLC-primed cells The ability of in vitro primed cells to lyse relevant allogeness target cells was possibly first increased (up to 2 weeks ATX) but markedly depressed from the week 3 onwards, and remained depressed to approximately 30% of the control level throughout the observation period of 90 d.

The depression of T-cell responsiveness to phytohaemagglutinin, con A and in the MLC and CML reactions may be explained by a decrease in the relative amount of T cells in the spleen, especially since the percentage of spleen  $\theta$ -positive cells decreases after ATX (refs 4 and 6 and C. Fournier and J. F. B., unpublished). The proportional decrease in the number of T cells, however, cannot explain our results since first, the responder cells have been passed through nylon columns before being used, which is known to remove macrophages and most non-T cells9 and, second, there is an obvious dissociation between the various T-cell functions quantitated. The enrichment of T cells afforded by nylon-wool filtration could explain the relaitively low depression of the proliferative response in the MLC found in this study as compared to earlier reports 13,14 (which in addition concerned two-way MLC).

Our results, as regards the temporary depression of T-cell mitogen responses following ATX, confirm the findings by Folch and Waksman on the effect of ATX on T-cell mitogen responses in the rat15. Our findings show a dissociation in the effects of ATX on the MLC and CML responses. The CML response seems to be more dependent on an intact thymus function than the MLC response. Howe has shown that anti-0 serum plus complement inhibited CML responses more readily than MLC responses, suggesting that the killer cell precursors had a larger amount of  $\theta$  antigen on their surface than the MLC proliferating cell precursors 16. Since ATX selectively depletes those spleen cells which express a high amount of  $\theta$  antigen on their surface (C. Fournier and J. F. B., unpublished), it may be that these cells are the precursors of CML effector cells.

The FITC-conjugated sheep anti-mouse Ig was a gift from Professor A. Fagraeus, State Serum Institute, Stockholm and the con A a gift from Professor H. Wigzell, University of Uppsala.

#### Ganglioside catabolism in hexosaminidase A-deficient adults

TAY-SACHS disease is an inborn error of glycosphingolipid metabolism characterised by the accumulation of N-acetylgalactosaminyl - (N-acetylneuraminyl) - galactosylglucosylcera mide (G<sub>M2</sub>) and N-acetylgalactosaminylgalactosylglucosylceramide (GA2) in various tissues of affected individuals1. A defect in the removal of N-acetylgalactosamine from G<sub>M2</sub>, catalysed by a hexosaminidase, has been demonstrated as the underlying deficiency in all forms of G<sub>M2</sub>-gangliosidosis<sup>2,3</sup>. In Tay-Sachs disease this defect has been associated with the absence of one (the A form) of the two major isozymes of β-N-acetylhexosaminidase (Hex A and Hex B)4. Hex A can be differentiated from Hex B in serum, leukocytes, cultured skin and amniotic fluid cells, and urine by using various physical characteristics of these enzymes<sup>5</sup>. The smaller proportion of A relative to B is the basis of screening for heterozygous carriers of Tay-Sachs disease<sup>6</sup>.

A deficiency of Hex A has been demonstrated in the healthy members of a family where other members have had Tay-Sachs disease7.8 and this is difficult to reconcile with the currently accepted interpretation of the absence of Hex A in Tay-Sachs disease. It has been suggested that this relationship can be clarified by studying the hydrolysis of labelled  $G_{\text{M2}}$  and  $G_{\text{A2}}$ in appropriate tissues from these clinically normal A-deficient adults. We report here the catalytic properties of leukocyte hexosaminidases from such individuals when the natural substrates,  $G_{M2}$  and  $G_{A2}$ , are used to measure activity. These levels are compared with those present in normal A-containing adults and Tay-Sachs heterozygotes and homozygotes.

Leukocytes were prepared from 20 ml of blood as follows9. Red cells were allowed to settle from whole blood at room temperature in a heparin-dextran solution. Plasma containing leukocytes and platelets was removed and centrifuged at 1,000g for 10 min. The pellet, containing white cells, was removed and subjected to osmotic shock to remove residual red cells and then recentrifuged. The resulting pellet was washed twice with physiological saline. The final white cell pellet was homogenised in 2.5 ml of 0.25 M sucrose in a tight-fitting all glass homogeniser and the homogenate was centrifuged in the cold at 1,500g. The supernatant was removed and used as the source of enzyme. Incubations were carried out with the substrate 4-methylumbelliferyl-β-N-acetylglucosamine7 or the specifically labelled natural substrates G<sub>M2</sub> and  $G_{A2}^{3}$  with the modifications noted in Table 1.

Leukocyte preparations from normal controls, Tay-Sachs heterozygotes and A-deficient adults all possessed enzymes able to degrade the artificial and natural substrates. Leukocytes from the Tay-Sachs homozygote possessed no catalytic activity toward  $G_{M2}$  as substrate but could degrade  $G_{A2}$ . Although the specific activity of G<sub>M2</sub> hydrolysis in the Tay-Sachs heterozygotes was lower than the A-deficient adults, and probably indicates some differences in the enzymes' active site, this difference in specific activity by itself may not be significant. There were no differences in the specific activities of the groups when artificial substrate was used to monitor total hexosaminidase activity. As previously shown, using the artificial substrate7 the A-deficient adults and Tay-Sachs homozygotes were phenotypically the same in their deficiency of the A form. All samples studied had catalytic activity toward GA2 with overlap in the specific activities between groups. By consideration of the ratio of G<sub>M2</sub> activity to G<sub>A2</sub> activity, it was possible to classify the heterozygotes as having a ratio of about one half of the normal controls. This type of classification is valid as no deficiency in GA2 hydrolysis is reported in Tay-Sachs homozygotes. When the same ratio was calculated for the A-deficient adults, similarities to the Tay-Sachs heterozygotes rather than to normal controls were obtained. It is believed, however, that these two heterozygous states may be fundamentally different as the lower G<sub>M2</sub>/G<sub>A2</sub> ratio in classic Tay-Sachs carriers seems to be due to a decrease in  $G_{M2}$  hydrolysing

<sup>\*</sup>See ref. 7.

activity, while in the A-deficient adults there is a combination of lower G<sub>M2</sub> and higher G<sub>A2</sub> hydrolysing activity. It was of interest to study the parents of the A-deficient adults who appear as Tay-Sachs heterozygotes by conventional criteria, to determine whether they might be classified by the evaluation of  $G_{\text{M2}}$  to  $G_{\text{A2}}$  activity. The mother with a ratio of 15 seems to be a true Tay-Sachs heterozygote; the father possesses an intermediate ratio, 29, and seems to be the carrier of a new mutation which was previously postulated by pedigree analysis.

It has been generally assumed that only Hex A is involved in  $G_{M2}$  degradation<sup>10</sup>. Significant amounts of  $G_{M2}$ -hydrolytic activity, however, have been demonstrated in homogeneous preparations of either Hex A or B from human placenta11. In these preparations, the kinetic properties of both hexosaminidases with this substrate were essentially identical. Although it is difficult to extrapolate from these data to the situation in vivo, the possibility that Hex B normally participates in G<sub>M2</sub> catabolism must be considered. If this is indeed the situation, then the loss of the A form and existence of individuals with no A should be expected. One of the correlates of this interpretation is the necessity of an abnormality in Tay-Sachs patients of at least the part of the hexosaminidase B component involved in G<sub>M2</sub> degradation. The data presented here are consistent with both the genetic model previously postulated7 and with the model for hexosaminidase relationship already proposed11,12 where A is a conformer of B or represents an independent modification of the B gene product.

These findings are also consistent with the common and unique subunit theory for the relation of Hex A and B13 but are not readily reconcilable to the specifier subunit theory13.

Finally, as long as enzymatic activity with artificial substrates alone is used to classify carriers and patients with Tay-Sachs disease<sup>5</sup>, it will be impossible to distinguish both the A-deficient adults from those with Tay-Sachs disease and their parents from typical Tay-Sachs carriers. The frequency of this subpopulation among Tay-Sachs carriers is not known and based on current methods of prenatal diagnosis14, the A-deficient adults would today be classified as Tay-Sachs patients.

#### Specific binding of growth hormone to thymocytes

As well as its general trophic effect on lymphoid tissue growth hormone (STH) specifically increases the activity of thymocytes in a graft versus host reaction and their helpe activity3. In vitro studies showed that STH alters the mitoti activity, RNA and protein metabolism of thymocytes\* At least for the effects obtained in vitro, it is assumed the STH binds to the thymocytes and thereby changes their physiological activity. The nature of this binding has no been studied. To learn about the characteristics of the surmised interaction, bovine STH (Nutritional Biochemical Cleveland, Ohio) and bovine prolactin (National Institute of Health, lot NIH B4) were labelled with 128 I and the binding to lymphoid cells was studied.

The labelling mixture contained 3 mg hormone, 200 µ lactoperoxidase (Sigma Lot No. 112c-0320), 100 μg glucose oxidase (Worthington, GOP 2 LA, 105 IU mg<sup>-1</sup>), 5 m glucose, 5×10<sup>-7</sup> M KI and 5 mCi carrier-free <sup>128</sup>I (Eidgeno sische Reaktorforschungs AG, Wuerenlingen) in 2 1 0.5 M phosphate buffer, pH 7.8. The reaction was carried

<sup>†</sup>Incubations contained 10 nmol of GalNAc-3H-G<sub>M2</sub> (16,000 c.p.m.), 50mM citrate-phosphate buffer (pH 4.4) and extract in a total volume of 200 µl. Incubations were for 3 h at 37° C and assay for GalNAc-3H released was as previously published<sup>3</sup>.

‡Incubations contained 10 nmol of GalNAc-3H-G<sub>A2</sub> (20,000 c.p.m.) 50 mM citrate phosphate buffer (pH 4.0), 0.24 mg sodium taurocholate.

and extract in a total volume of 200 µl. Incubations were for 1 h at 37° C and GalNAc-3H released was assayed as before.

out at room temperature for 20 h with constant stirring. A slight precipitate was removed by centrifugation; STH was then precipitated by the addition of 3 ml 1 M phosphate buffer, pH 7.0, prolactin by the addition of 2.2 ml saturated ammonium sulphate, pH 7.0, the precipitates collected and redissolved in 2 ml 0.05 M phosphate buffer, pH 7.8. This procedure was repeated four more times. The final supernatant contained negligible amounts of radioactivity. The precipitate was assumed to contain only hormone, since in preliminary trials the enzymes used did not precipitate in the conditions described. The protein concentration of the final solution was determined by optical density readings at 2800 Å, and the radioactivity of an aliquot determined. From this, a specific activity of  $5 \times 10^{16}$  d.p.m.  $mol^{-1}$  STH was calculated. Prolactin was labelled to the same extent.

Cell suspensions were prepared from calf thymus and brachial lymph nodes, obtained from the local slaughter-house within 15 min of killing the animal. Mouse thymus, mesenteric lymph nodes and thymus from mice injected 2 d previously with 2 mg of hydrocortisone were obtained from C3H/eb mice. The lymphoid organs were cut with scissors into fine pieces in cold Hank's balanced salt solution (BSS) and then squashed with a Teflon pestle against the walls of a loose fitting tube. Tissue debris was left to settle and the

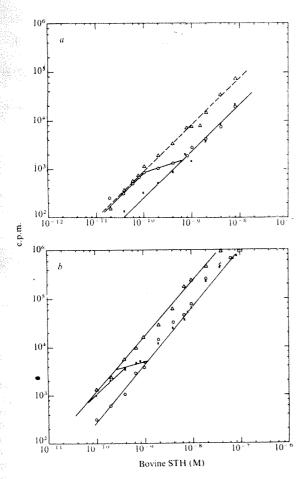

Fig. 1 a, Binding of bovine STH to bovine thymocytes (TC) and lymph node lymphocytes (LNC). Triplicate samples of  $2.5 \times 10^6$  cells were incubated in the cold for 15 min in 2 ml Hank's balanced salt solution containing labelled hormone at the indicated concentration. They were then spun down, 1 ml of the supernatant counted in a  $\gamma$  counter with an efficiency of 46%. Also, 1 ml of the hormone dilutions was counted to give the total c.p.m. added ( $\Delta$ ). The arithmetic mean of the differences between corresponding tubes containing cells and supernatant and only supernatant is given as c.p.m. bound to cells;  $\bigcirc$ , c.p.m. on bovine TC;  $\times$ , c.p.m. on bovine LNC. b, Binding of bovine STH to murine TC and LNC.  $\triangle$ , total c.p.m. added;  $\bigcirc$ , c.p.m. bound to mouse LNC;  $\times$ , c.p.m. bound to mouse TC.

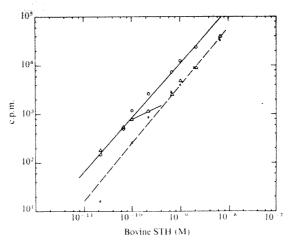

Fig. 2 Inhibition of binding of STH to murine thymocytes (TC) by pretreatment with an excess of STH or prolactin. Murine thymocytes were incubated in unlabelled hormone at a concentration of 10<sup>7</sup> cells per 10 μg hormone ml<sup>-1</sup> (15 min at 4°C) and washed twice with BSS. The rest of the procedure was as described in the legend to Fig. 1. Δ, c.p.m. on mouse TC, preincubated in bovine prolactin; (), total c.p.m. added; ×, c.p.m. on mouse TC, preincubated in bovine STH.

supernatant cell suspension was then washed once with cold BSS. Cell viability, as estimated by trypan blue exclusion, was over 90%. Cells were then incubated with decreasing amounts of labelled hormone in the cold and spun down. The radioactivity of half the supernatant was determined and separately that of the cell pellet with the other half of the supernatant. Differences in counts obtained were taken as evidence that hormone had bound to the cells and were used to estimate the amount of hormone bound by the cells (Fig. 1). It was found that bovine and murine lymph node cells (LNC) bound, at all the concentrations tested, about one third of the total amount of either STH (Fig. 1) or prolactin added (data not shown). Hydrocortisone-resistant murine thymocytes were similar to LNC in their binding behaviour. Normal thymocytes bound about the same fraction of the hormone at concentrations above 10-9 M; below that, however, they took up increasing proportions of the total STH present, but not of prolactin. At about 10<sup>-10</sup> M all the STH was associated with the cells. In contrast, prolactin was bound with decreasing efficiency by thymocytes at all concentrations below  $5 \times 10^{-10}$  M.

The binding of all the STH added to thymocytes at low concentrations could be reduced by about two-thirds by preincubating the cells in unlabelled STH (Fig. 2). Preincubation in unlabelled prolactin (Fig. 2) or thyroxin (2  $\mu$ g per  $10^{-7}$  cells in 2 ml BSS, 15 min at 4° C) had no effect upon the binding of STH to either LNC or thymocytes.

It therefore seems that there are two mechanisms by which STH binds to thymocytes: one demonstrable at high concentrations of the hormone, that is above 10° M, the other at physiological concentrations. The first one would account for the binding of about 1/3 of all the hormone added; it seems to be unspecific and not saturable, since binding could not be inhibited by preincubation of the cells in unlabelled STH or prolactin. This type of binding was also observed with lymph node lymphocytes and hydrocortisone resistant thymocytes. The other type of binding, observable at physiological concentrations of STH and below, seems to be saturable and specific, since it could be inhibited by preincubation of thymocytes in unlabelled STH but not of the structurally similar prolactin<sup>6</sup>. This binding is probably also of high affinity, since thymocytes incubated in labelled growth hormone (10<sup>7</sup> cells per 10 µg STH per ml, BSS, 15 min at 4° C) will, upon prolonged washing (12 centrifugations over a period of 24 h) retain an amount of

radioactivity per cell equivalent to that found at 10<sup>-9</sup> M STH in the dilution assay. In these conditions, lymph node cells shed all the radioactivity bound initially.

These data fit well with the assumption of specific receptors for STH being present in the thymocytes membrane.

The maximal amount of hormone taken up by the thymocytes through these postulated receptors can be estimated from Fig. 1, assuming saturation of the receptors at that concentration of hormone, when radioactivity first appears in the supernatant. From the specific activity of the hormone, the total number of cells in the incubation mixture, and the efficiency of counting, it may be calculated that about 10,000 molecules of STH were bound to one calf thymocyte and 20,000 to a murine thymocyte (average of three independent experiments, yielding, respectively, 18,000, 20,000 and 22,000). Whether this represents indeed the number of high affinity, specific binding sites on thymocytes is not clear as some of them may be occupied by endogenous hormone bound previously in vivo. The number of receptors may thus be substantially higher.

Specific binding of STH to cells has previously been demonstrated with human lymphocytes grown in vitro7 Whether the binding of STH to lymph node lymphocytes influences their physiological state is unknown. It is also unknown which part of the binding of STH to thymocytes induces changes in their metabolism in vitro and whether this is related to their biological activity2

I thank Dr R. Citronbaum for help with the radioiodination procedure, Dr N. K. Jerne for his hospitality at the Basel Institute for Immunology and Dr R. Bates of the National Pituitary Agency for supplying prolactin. This work was supported by the Schweizeriche Nationalfond zur Foerderung der wissenschaftlichen Forschung and the Emil Barrell-Stiftung.

#### Initiation of polyphenylalanine synthesis and the action of cytokinins in fenugreek cotyledons

THE initiation of peptide chain formation is thought to be the point of control in protein synthesis. Plant growth hormones may also act at this point.

Isolated cotyledons of fenugreek (Trigonella foenum-graecum L.) respond to cytokinins1 and it has become evident that at an early stage the growth response in darkness is dependent on protein synthesis. It has been shown that cytokinin treatment of cotyledons increases the activity of the ribosome fraction in

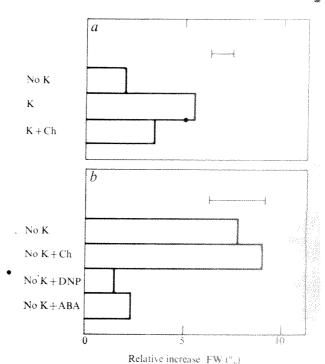

Fig. 1 Cotyledons (five per dish) were weighed before and after incubation at 25° C in darkness in Petri dishes (six replicates per treatment) on filter paper wetted with 20 mM KNO<sub>2</sub> and other compounds as indicated. Antibiotics used were penicillin, streptomycin and mycostatin, 25 µg ml<sup>-1</sup> each. LSD values at P=0.01 are shown. a, Stimulation of fresh weight increase of cotyledons after 6 h application of  $5\times10^{-6}$  M kinetin (K) and inhibition of this stimulation by 10  $\mu$ g ml<sup>-1</sup> cycloheximide (Ch), b, Inhibition of fresh weight increase after 47 h in the control (no kinetin) situation by  $5 \times 10^{-6}$  M dinitrophenol (DNP) and 5×10<sup>-7</sup>M abscisic acid (ABA) but not by 25 μg ml<sup>-3</sup> cycloheximide.

in vitro protein synthesis2. The ribosomes from treated coty ledons are more active in initiation of poly(U)-directed poly phenylalanine synthesis.

Cotyledonary petioles with enclosed plumules and radicle were removed from dry fenugreek seed by making two cuts The cotyledon containing parts were sterilised, washed, an incubated overnight in Petri dishes on moist filter paper. Th cotyledons were then isolated and subjected to a preliminar 24 h incubation in control conditions (20 mM KNO<sub>3</sub>, 50 µ ml-1 chloramphenicol) before such treatments were applied Other antibiotics were used, however, in some experiment (Fig. 1). Neither these antibiotics nor chloramphenicol affectes the growth response. From sterilisation onwards, the materia was in darkness except for manipulations carried out unde green safe light.

The growth response to cytokinins at its earliest observable stage seems to depend on protein synthesis. A stimulation of relative fresh weight increase (expansion) after 6 h of kineth application is shown in Fig. 1a; this stimulation was reduced significantly by cycloheximide at 10 µg ml<sup>-1</sup>. In contrast, ever after 47 h, the 'slow expansion' in the absence of cytokining was not inhibited by cycloheximide at 25 µg ml<sup>-1</sup>, (Fig. 1h) of a 10 μg ml<sup>-1</sup> (ref. 3). This is noteworthy because in the control condition, protein synthesis takes place and is inhibited by cycloheximide, and because the 'slow expansion' in the control condition is severely inhibited (Fig. 1b) by either dinitrophenol (5  $\times$  10<sup>-5</sup> M) or abscisic acid (5  $\times$  10<sup>-7</sup> M). Therefore cytokinin-induced growth in these cotyledons seems linked in a special manner to protein synthesis.

Significant effects on incorporation of amino acids have been observed 3, 2 and even 1 h after cytokinin application. In one experiment an increase of 48% of 14C-leucine incorporation into protein due to kinetin treatment was observed at the end of a 3 h incubation. In that experiment, cycloheximide (10 µ ml-1) inhibited incorporation in both the control and kinetir treatment to 16% of the uninhibited control value. Kinetin die

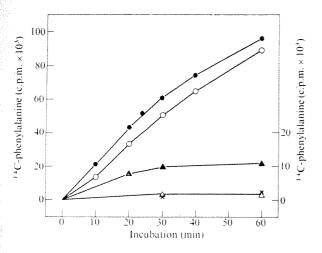

Fig. 2 <sup>14</sup>C-phenylalanine incorporation with time in an *in vitro* incorporation system without poly(U)(×), with poly(U)(○), and the same but after 5 min preincubation at 30° C of tRNA, poly(U) and ribosomes (♠). Aurintricarboxylic acid (5 μg) added at time zero (△) or after 5 min of preincubation on ice of tRNA, poly(U) and ribosomes (♠). Extracts were prepared by grinding lots of 100 cotyledons with mortar and pestle to a final volume of 12 ml of 0.1M Bis-Tris (bis (2-hydroxyethyl) amino tris (hydroxymethyl) methane) (Sigma) HCl, pH 7.8, 40 mM KCl, 10 mM MgCl<sub>2</sub>, 1 mM dithiothreitol. They were then centrifuged for 20 min at 18,000g and after addition of 200 μl 25% Triton X-100 the post-mitochondrial supernatants for 1 h at 160,000g. 5 ml of supernatant were dialysed for 2–3 h against 1 l of buffer; the 160,000g pellet was resuspended in buffer and centrifuged for 90 min at 160,000g. The pellet was again carefully resuspended, this time in about 2.5 ml of buffer and centrifuged once more at 5,000g for 5 min as was the dialysed supernatant. The absorbances at 260 nm were read and corrections made for differences by dilution. Assay: 30 min, 30° C, 0.5 ml total volume, buffer 0.1 M Bis-Tris pH 7.8, KCl 40 mM, MgCl<sub>2</sub> 10 mM, dithiothreitol mM, poly(U) 50 μg, tRNA (E. coli) 100 μg, ATP 1.2 μmol, GTP 0.1 μmol, PEP 1 μmol, pyruvate kinase in 4 M (NH<sub>4</sub>)<sub>2</sub> SO<sub>4</sub> (Sigma) 1 μl, ribosomes 2.5 A<sub>280</sub> units, supernatant 2.5 A<sub>280</sub> units. <sup>14</sup>C-phenylalanine 0.5 μCi, (522 mCi mmol<sup>-1</sup>). Stopped with TCA, heated and washed on to glass filter disks, digested with NCS solubiliser, and counted in toluene 2.5-diphenyloxazole scintillant mixture. \* No poly(U).

mot affect uptake but cycloheximide did; presumably this was a side effect of the inhibition of protein synthesis, as the inhibition of incorporation into protein was far in excess of that of uptake. In a repeat experiment, the 70% ethanol extractable amino acid content per cotyledon (4.7 s.e. 0.1 μmol) was not affected by the kinetin treatment.

In an earlier analysis using an *in vitro* protein synthesis system, it seemed that kinetin treatment of the cotyledons increased the activity of the ribosome fraction rather than that of the post ribosomal supernatant and its tRNA<sup>2</sup>.

My in vitro amino acid incorporating system used vashed, Triton-treated ribosome and dialysed high-speed supernatant fractions. The supernatant used throughout was derived from control cotyledons but the ribosomes were from either control or cytokinin-treated cotyledons and corrected or differences in concentration (see legend to Fig. 2).

Incorporation in the poly(U)-directed assay system proceeds inearly with time for about 30 min, or it may show an initial ag; but, if poly(U), ribosomes and tRNA are preincubated in buffer together, the initial lag in incorporation is removed when the other components of the assay system are added Fig. 2). This suggests the requirement for an initiation step in polyphenylalanine synthesis, in which a ribosome-poly(U) complex is formed<sup>4</sup>. The initiation process may be stopped nearly completely and specifically in plant systems<sup>5</sup> at any time by addition of  $2 \times 10^{-5}$  M aurintricarboxylic acid (ATA); applied at zero time it removes the effects of poly(U) addition (Fig. 2). Although a preincubation, carried out at  $0^{\circ}$  C, did not seem to semove the initial lag, such preincubation does seem to afford

Table 1 Effect of treatment of cotyledons with various cytokinins for 3 h (experiment 1) with kinetin and inhibitors (experiment 2) on initiation activity

Activity expressed as difference in incorporation of <sup>14</sup>C-phenylalanine after 30 min incubation of a poly (U)-directed system with €×10<sup>-5</sup> M aurintricarboxylic acid added at time zero but with and without a preincubation of poly(U), tRNA and ribosomes for 5 min on ice as in Figs 2 and 3. Control supernatant was used in all incubations.

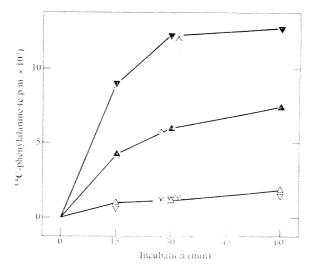

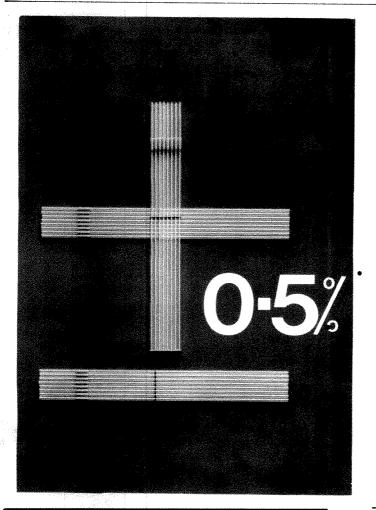

Fig. 3 Measurement of initiation activity of ribosomes from control ( $\triangle$ ) and  $5 \times 10^{-5}$  M, 3 h, kinetin-treated ( $\nabla$ ) cotyledons as difference (arrows) in incorporation of <sup>14</sup>C-phenylalanine in a poly(U)-directed system with aurintricarboxylic acid added at time zero but with ( $\triangle$ ) and without ( $\triangle$ ) 5 min preincubation on ice of tRNA, poly(U) and ribosomes, as in Fig. 2, but during incubation only control supernatant used.

measurable initiation activity: ATA, applied after a 5 min initiation preincubation of poly(U), ribosomes and tRNA on ice, allows some extra incorporation during the subsequent elongation—incubation period (Fig. 2).

A measure of the initiation activity is obtained by the difference between incorporations in incubations which had or had not followed preincubation of ribosomes, poly(U) and tRNA for 5 min on ice and to which ATA had been added at time zero (Fig. 3). Table 1 shows the relative values in initiation activity using ribosomes from cotyledons treated in different ways. The activity is increased considerably after treatment for 3 h with kinetin, zeatin or 6-benzyladenine, but notably not by 6-methyladenine, a base which at the applied concentration does not elicit a growth response<sup>1</sup>.

No increase in initiation activity, however, has been observed following *in vitro* treatment of control ribosomes with zeatin ( $10^{-6}$  M) or with 6-benzyladenine ( $5 \times 10^{-6}$  M). The increase in activity of ribosomes from kinetin treated cotyledons is pre-

## Now use 'Pyrex' oncethrow away and save!

Corning disposable micro-sampling pipettes are made from Pyrex brand borosilicate glass. They have greater strength and reproducibility. The accuracy of the graduated 5 Lambda ( $\lambda$ ) is  $\pm$  1%. The others have an accuracy of ± 0.5%. All are individually colour coded for ease of identification.

Range:  $5\lambda$  (graduated in  $1\lambda$ 's), 5, 10, 20, 25, 50, 100λ, and 44.7λ sodium heparinised.

## Collected

These specially designed Binders make attractive space-saving files for your Nature. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of Nature. Two volumes of Nature can be preserved in a single binder (three binders will hold the six volumes published annually), and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains. These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road. Basingstoke, Hampshire RG21 2XS.

#### Lipmann-Symposium: Energy, Biosynthesis and Regulation in Molecular **Biology**

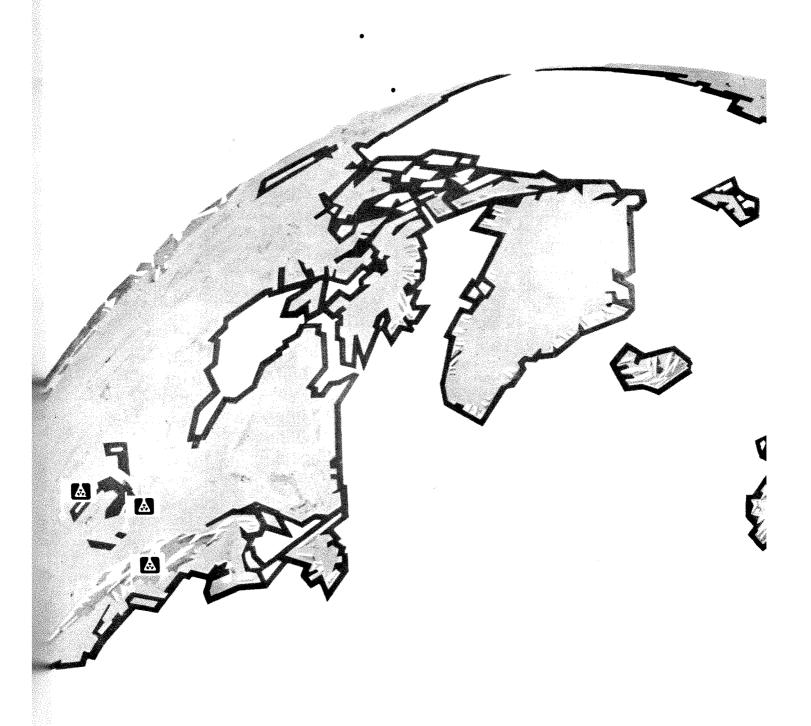

**Editor: Dietmar Richter** 

1974. Large-octavo. XX, 701 pages. Bound DM 150,-; \$ 57.70 ISBN 3 11 004976.

This volume covers the symposium which was held in honour of Fritz Lipmann's 75th birthday. It contains about 60 contributions by former affiliates and other leading scientists such as Lynen, Sir Hans Krebs, Ochoa, Lipmann, Vazquez, Moldave, Weissbach, Ebashi to name only a few. The contributions cover a broad field and range from energy transfer to non-ribosomal peptide synthesis, from amphibian cell culture to transmitter biochemistry, from gene regulation to insect immunity, from structure and functions of ribosomes to cyclic AMP, from regulation of muscle contraction to stringent and relaxed control mechanism. The volume also contains an account of scientific and social life in Berlin-Dahlem in the late nineteen twenties by Sir Hans Krebs and Fritz Lipmann, two "insiders"

### **Oxford Books for Students**

## What is Ecology?

D. F. Owen

Ecology is concerned with exponential growth, the control of population size, and the structures of communities and ecosystems. The author explains how ecology affects us and our supplies of food, oil, and other raw materials. His book will guide readers to think as ecologists and to make sensible predictions about the future. £2.75 paper covers 95p OPUS

## Essentials of Organic Nomenclature

A Programmed Course

John B. Jepson and William R. D. Smith

All students of the life sciences and medicine must have a working knowledge of organic nomenclature so that they can relate structures and names of biologically active materials to functional properties. This learning programme aims to bring students with only the most elementary knowledge of chemistry to the point where organic names no longer appear intimidating, and instead begin to explain properties and reactions. It will be useful to sixth-formers, medical and dental students, and first-year undergraduates studying chemistry or biology. Paper covers 50p

# Guthrie and Honeyman's Introduction to Carbohydrate Chemistry

Revised by R. D. Guthrie

The text of this book, a compact introduction to the chemistry of carbohydrate substances, has been completely restructured, rewritten, and up-dated. Some classical carbohydrate chemistry has been omitted and this has enabled the section on glycosides to be expanded, carbohydrate antibiotics to be introduced, and a new chapter on structural studies and systems to be added. The physical techniques chapter now includes a section on 13C n.m.r. spectroscopy, and another new feature is the extensive use of Mill's representation for sugar structures rather than the more usual Haworth formulae. Fourth edition £4 paper covers £1·50

## Introduction to Control Theory

O. L. R. Jacobs

This book gives a uniform presentation of the main results of classical control theory, optimal control theory, non-linear methods, and stochastic control theory. The mathematical level is that of final-year undergraduate courses in engineering science, but the book is accessible to anybody with some knowledge of ordinary linear differential (or difference) equations, the elements of probability theory, complex numbers, and matrix algebra. £6.75

### **Our Future Inheritance**

Choice or Chance?

### Alun Jones and Walter F. Bodmer

Recent advances in genetics, biology, and medicine have important social, ethical, and legal implications as well as being of great scientific importance. This book is concerned with some of the most significant topics: artificial insemination and fertilization of humans, genetic screening and selective abortion, organ transplantation, genetic engineering and cloning. The issues are presented dispassionately and clearly. £4 paper covers £1·25

## Principles and Problems in Physical Chemistry for Biochemists

 Nicholas C. Price and Raymond A. Dwek

Student biologists and biochemists are here introduced to physical chemistry by means of worked examples and problems (with detailed answers) and brief, concise explanations of the most important theoretical points. The text is developed logically and shows the student how it is possible, by using thermodynamic quantities, to predict whether a process can occur, and from kinetic studies to predict how fast this will happen. £5 paper covers £2

## Mathematical Analysis and Techniques

A. Page

This treatment of analysis is based on the needs of students taking mathematics as part of a degree or HND in science or engineering. It also provides a textbook for those interested in the practice of mathematics and a useful introduction to the more abstract texts. The subjects covered include, in Volume I, functions of two or more variables and double integrals and, in Volume II, differential equations, matrices, and functions of a complex variable. Two volumes £2·50 each Oxford Mathematical Handbooks

## A First Course in Combinatorial Mathematics

Anderson

This is an introduction to the basic combinatorial tools such as recurrence relations, generating functions, incidence matrices, and the inclusion-exclusion principle. A study of block designs is followed by a brief mention of applications to coding theory, and in the final chapter Steiner systems and sphere-packing problems are related via the famous Leech lattice. The book is intended for undergraduates at universities and polytechnics, and, apart from the last chapter, it provides a standard course for such students with plenty of examples to work on. £3·75 paper covers £1·35 Oxford Applied Mathematics and Computing Science Series

## **Oxford University Press**

vented by the presence of 2,4-dinitrophenol for 20 h during the treatment of the cotyledons receiving kinetin during the last 3 h only (Table 1). This suggests that the kinetin effect on initiation activity requires energy.

For mammalian ribosomes, binding of poly(U) to the small subunit at 0° C has been shown to be dependent on the presence of associated protein. For this protein, which is removed by a 0.5 M KCl wash, initiation-factor function has been suggested. In several experiments, not detailed here, the presence of 0.5 M KCl in the buffer used for resuspending the ribosomes after the first high speed centrifugation, about halved the initiation activity of the ribosomes, which after the second high speed centrifugation were resuspended in standard buffer. A way in which the present kinetin-induced increases in initiation activity may be explained is as an increase in the concentration or as an activation of protein initiation factors.

My findings may help to explain the function of the reported binding of cytokinins to ribosomes7. Such binding by itself, however, does not seem sufficient to explain the observed increase in initiation activity. An improvement of the ribosome fraction has been observed for auxin treated soybean hypocotyl segments and it was suggested that this implied an enhanced level of peptide chain initiation<sup>8</sup>.

I thank Mrs L. Eckhardt for technical assistance and Dr J. A. Zwar for correcting the text.

Addendum: In the experiment of Fig. 2 the ribosomes were prepared from freshly dissected cotyledons as such ribosomes seem to show the lag period more readily.

#### A receptor mediating sexual differentiation?

SEXUAL differentiation of the brain is believed to be mediated by exposure to testicular androgens at a critical period of development-prenatal in most species, but during the first 5 d after birth in rats. Only those androgens which are potential substrates for aromatising enzymes (that is, those which can be converted to oestrogens in vivo) are effective1-4. These observations led to the concept that masculinisation of the brain is caused by local conversion of androgens to oestrogens.

There is now a considerable amount of evidence in support of this hypothesis. For example, the masculinising effects of androgens on the brain can be prevented by the previous administration of the antioestrogen MER 25 (ref. 5), and the effects of oestrogens, administered during the critical period, are similar to those of androgens<sup>6-9</sup>. Aromatising enzymes are present in the hypothalamus and amygdala<sup>10</sup> and in vivo conversion of 3H-androgen to 3H-oestrogen has been shown

in these areas during the critical period11.

Are oestrogen receptors present in the brain during the critical period? Previous attempts12 to answer this question have been hampered by the presence of large amounts of a specific oestrogen-binding protein (blood EBP)13 in the plasma of perinatal animals. Neonatal rat brain contains a similar protein (brain EBP)14 which is present in high concentrations and is possibly extracellular. It is distinguished from the oestrogen receptor of the adult brain15 by its relatively low affinity  $(K_d \sim 10^{-8} \text{ M})$  for oestradiol and by the inability of diethyl-stilboestrol (DES) to compete with oestradiol-17β in the binding reaction.

Here we report the use of a new and sensitive method<sup>15</sup> to estimate the high affinity binding of oestradiol by cytosol from the brains of neonatal rats. We chose our experimental conditions so that we measured only slowly dissociating, high affinity, DES suppressible binding; the low affinity EBPs of blood and brain were not detectable.

Wistar rats (5 d old) of both sexes were used and binding was estimated in cytosols prepared from two areas of the brain: (HA) which contained both hypothalamus and amygdala, and (C) which contained cerebral cortex. Scatchard<sup>17</sup> representations of binding isotherms (Fig. 1) were apparently rectilinear: this is consistent with the measurement of a single class of noninteracting binding sites. Dissociation constants of the reaction were similar to those of the adult receptor, about 10<sup>-10</sup> M (Table 1).

The distribution, however, was different. In the adult the

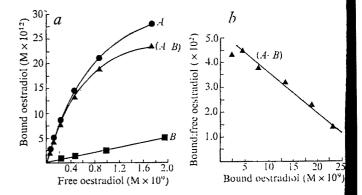

Fig. 1 a, The binding of <sup>3</sup>H-oestradiol to cytosol from brain of 5-d-old rats; cytosol was from a female in this example. Cytosol (110,000 $g \times 1$  h; phosphate buffer, pH 7.3) samples Cytosoi (110,000 $g \times 1$  n; phosphate duffer, p = 7.3) samples were incubated with various concentrations (2 × 10<sup>-9</sup> M to 2 × 10<sup>-10</sup> M) of 2, 4, 6, 7 <sup>3</sup>H-oestradiol-17g (100 Ci mmol<sup>-1</sup>) for 30 min at 30° C. Control incubations contained, in addition, an excess, (10<sup>-7</sup> M) of unlabelled DES. 0.2 ml fractions were placed on small columns  $(0.45 \times 10 \text{ cm})$  of Sephadex LH-20 in buffer, maintained at  $0-4^{\circ}$  C. Samples were washed with 0.2 ml buffer and allowed to remain in contact with the gel for 150 min before they were eluted (0.7 ml), and bound radio-activity estimated. A, total binding; B, binding in the presence of excess DES; (A-B) DES suppressible binding, obtained by subtraction. b, Scatchard representation of A-B. We detected no DES suppressible binding in either blood or heart cytosol.

receptors are most concentrated in hypothalamus and amygdala and are relatively sparse in cortex. In the brain of the neonatal animal equal amounts of high affinity oestrogen binding material were found in both HA and C and in both sexes (Table 1); concentrations were similar to those of the receptor in the adult female hypothalamus. The binding material is, a least in part, protein: incubation with pronase, but not with DNase or RNase, destroyed its ability to bind oestradiol Binding activity was reduced after incubation with protamine sulphate or with p-hydroxymercuribenzoate. Thus the protein is similar to the adult receptor in that it is acidic, and the

Table 1 Distribution and dissociation constants of reaction (K<sub>d</sub>) of DES suppressible, high affinity binding of <sup>3</sup>H- oestradiol-17β, in cytosol from brain of 5-d-old rats

	Abundance of oestradiol	binding sites	Reaction dissociation constant			
	Sites $g^{-1}$ wet weight ( $\times 10^{-10}$ )		$K_{\rm d}   imes  10^{10}   ({ m M})$			
	Hypothalamus Amygdala	Cortex	Hypothalamus Amygdala	Cortex		
Adult female	$19.8 \pm 1.2$ $8.3 \pm 0.4$	$1.8 \pm 0.3$	$1.5 \pm 0.3$ $1.08 \pm 0.16$	$1.7 \pm 0.6$		
5-d-old female	$11.8 \pm 1.8$	$13.4 \pm 1.1$	$6.1 \pm 1.2$	$6.4 \pm 1.5$		
5-d-old male	$10.7 \pm 1.0$	$15.9 \pm 1.9$	$5.7 \pm 0.6$	$6.3 \pm 1.0$		

Data are compared with values for binding in cytosols from brain of adult female rats<sup>15</sup>. Parameters were calculated from Scatchard representation of binding isotherms. Avogadro's number was used in the calculation of the number of binding sites. Values represent means  $\pm$  s.e.m. of at least five observations.

Table 2 The specificity of the binding reaction in cytosol from brains of 5-d-old rats compared with that of the receptor of the adult female

Dissociation constants of reaction were calculated from the suppression in the presence of unlabelled test substances of binding of 3H-oestradiol in the conditions specified in the legend to Fig. 1. Where standard errors are quoted the data are the mean values of four observations. Testosterone, 5α-dihydrotestosterone, progesterone, corticosterone and cyproterone (10-6 M) had no effect on the binding of <sup>3</sup>H-oestradiol.

integrity of -SH groups is important for the binding reaction.

The specificity of the reaction is the same in both areas and in both sexes and is broadly similar to the adult receptor (Table 2): potent oestrogens have high, and non-oestrogenic steroids have low binding affinities.

The low affinity for MER 25 of both the oestradiol receptor of adult hypothalamus and the oestrogen binding material from neonatal brain is somewhat surprising; however, MER 25 is an effective antioestrogen only when administered in high doses<sup>16</sup> and it protects the brain against masculinisation only when given some time before exposure to androgen<sup>5</sup>.

The affinities of the protein in brain cytosol from 5-d-old rats for oestradiol-17β and for oestrone are apparently lower than those of the adult (Table 2): but these differences may be artefacts due to the presence of brain EBP in the incubation medium.

The high binding affinities of the synthetic oestrogens DES and Ru 2858 are particularly interesting. Both compounds have a low affinity for blood EBP (ref. 13) and both affect the developing brain in a manner similar to that of oestradiol. Ru 2858, at least, is very much more potent than oestradiol-17β in its effects on the developing brain (C. Doughty, unpublished).

We propose that the high affinity, oestrogen-specific binding protein of neonatal brain cytosol is a receptor which is involved in the sexual differentiation of the central nervous system. Recent autoradiographic work<sup>12</sup> supports this view. After injection of 3H-oestradiol into newborn female rats radioactivity was concentrated in the nuclei of cells in the hypothalamus and amygdala: uptake was inhibited by concurrent administration of oestradiol or testosterone, but not by unlabelled 5α-dihydrotestosterone, which cannot be converted to oestrogen in vivo.

The role of the putative cytoplasmic receptor of the neonatal cortex has yet to be determined. As aromatising enzymes are absent in the cortex it is unlikely to be involved in the normal

process of masculinisation but may be involved in a, so far undefined, organising effect of oestradiol itself.

This work was supported by the Medical Research Council.

#### APPOINTMENTS VACANT

#### THE FACULTY OF MEDICINE OF MEMORIAL UNIVERSITY OF NEWFOUNDLAND

will appoint an Endocrinologist to its Basic Sciences Division in 1975. Individuals with research in-terests in metabolic regulation, neuroendocrinology or membrane studies will be considered.

Interested applicants should send resumé and names of three referces to:

Dr. Bruce H. Sells
Laboratories of Molecular Biology
Faculty of Medicine
Memorial University of Newfoundland
St. John's, Newfoundland

Before December 15, 1974.

(1755)

#### UNIVERSITY OF ALBERTA DEPARTMENT OF ZOOLOGY Edmonton, Alberta T6G 2E1, Canada

Edmonton, Alberta T6G 2EI, Canada

Two positions are available as Assistant or Associate Professor, from July 1, 1975. A specialist in some aspect of invertebrate zoology is needed to take major responsibility for teaching in a general course in invertebrates. A specialist in vertebrate morphology and vertebrate paleontology; an interest in fishes is preferred. In both positions there will be opportunity for teaching at advanced levels. Strong research orientation and Ph.D., or equivalent, is required. Salary will be within the range Can \$13,440 to 23,416. Applicants send a curriculum vitae and the names of three referees to Dr. J. R. Nursall, Chairman, Department of Zoology, before January 31, 1975. (1756)

#### THE HORMEL INSTITUTE OF THE UNIVERSITY OF MINNESOTA invites applications from qualled individuals for the position of

#### EXECUTIVE DIRECTOR

EXECUTIVE DIRECTOR

of the Hormel Institute which is located in Austin, Minnesota. The Executive Director is responsible for overall administration of an institute with 80-90 employees, including 20 of whom have academic rank. Candidates for this position should be recognized authorities in the lipid field, and should have at least 12 years of research experience in the field. The director is expected to maintain an active research program. Closing date for receipt of all materials is February 1, 1975. Send Curriculum vitae, a list of publications and names of three referees to Dr. J. E. Gander (Chairman, Search Committee), Department of Biochemistry, University of Minnesota, St. Paul, MN 55108. (1757)

#### UNIVERSITY OF BIRMINGHAM TECHNICIAN GRADE 3

A Research Technician is required to assist in a Neurochemistry laboratory, in the Neurocommunications Research Unit. The work involved would mainly be biochemical with some physiological and animal experimentation. Some laboratory experience essential and preference will be given to applicants with a degree or O.N.C. in Chemistry or a Biological subject.

Apply:

Assistant Secretary, University of Birmingham, P.O. Box 363, Birmingham B15 2TT.

(1763)

Ref. 581/C/579.

## **International Consultants**

## Tropical Agriculture

Bookers Agricultural and Technical Services manage sugar estates and provide a wide range of consultancy services for sugar and other agro-industrial projects. Assignments have been undertaken in over thirty-five countries on behalf of the World Bank, UN Agencies, ODM, overseas governments and

Further growth has created career opportunities for qualified AGRICULTURALISTS and AGRICULTURAL ENGINEERS who can make a significant contribution to agricultural expansion in developing countries. The work, which involves both agricultural planning and large-scale project development, requires frequent travel, with periods of overseas residence as

Candidates, ideally 32-45, should have a minimum of ten years' broadly-based agricultural experience, of which not less than five years should have been spent in non-temperate regions. A first-hand knowledge of the sugar industry would be valuable.

The appointments carry attractive salaries, overseas and travel allowances as appropriate, and substantial fringe benefits.

Please send brief career and personal details in the first instance to:

E. C. Robinson, Personnel Director, Bookers Agricultural and Technical Services Limited, Bucklersbury House, 83 Cannon Street, London EC4N 8EJ.

(1851)

## **Basic Grade Biochemist**

Required in the Biochemistry Department at the Royal Infirmary. The department is well equipped with a range of automated and manual instrumentation. It serves approximately 3,000 beds, including specialist units, and all General Practitioners. There are five other graduate staff. Previous experience is desirable but not essential.

The candidate appointed will be required to undertake studies leading to a professional or academic higher degree. Attendance at scientific meetings of the Association of Clinical Biochemists and at courses leading to further qualifications will be encouraged. Whitley Council salary scale and conditions of service. Removal expenses where appropriate can be paid.

Applications to Personnel Officer, Victoria House, Park Street, Hull.

Further enquiries and for engagements to visit the Laboratory, contact Dr L. B. Roberts, 0482-28541, Ext.

## STATE OF KUWAIT KUWAIT UNIVERSITY

#### ACADEMIC POSTS FOR 1975-1976

Applications are invited for the posts of Lecturers, Assistant Professors, and Professors. Contracts start on September 1, 1975, for two years. Renewable for a further period of four years if convenient to both applicant and university.

Applicants should be:-

- (A) Holders of an academic post at present in an accredited university or research center.
- (B) Ph.D. holders.

Application and curriculum vitae form with particulars of salary and other matters, are obtainable from Kuwait Embassies in Washington D.C. (4301) Connecticut Avenue, N.W., Site 158, Washington D.C. 200083 and London Cultural Attache Office, Al-Jahra House, 3 Stratford Place, London WIN 9AE, or from Kuwait University, Kuwait. Completed applications, together with a copy of the candidate's publications, must be received by 'Kuwait University, Kuwait', not later than December 15, 1974. Those who applied last year and this year can renew their applications by writing to the university.

Candidate is also entitled to the following privileges:

- 1. Annual return air tickets to this country, would be provided to him, his wife and three of his children not exceeding the age of twenty.
- 2. Free furnished accommodation with water and electric

#### UNIVERSITY OF GUELPH DEPARTMENT OF CHEMISTRY **FACULTY POSITION**

Applications are invited for a faculty position in the area of biochemistry or biophysical chemistry at the rank of assistant or associate professor, to begin September 1, 1975. Candidates must have a Ph.D. degree in chemistry or biochemistry and at least one year of postdoctoral experience in biochemistry or biophysical chemistry. Duties will include undergraduate and graduate teaching in biochemistry, supervision of graduate research, and independent research. Salary and rank will depend on qualifications and experience.

Applicants should provide a full curriculum vitae, transcripts of academic record, a brief description of research interests and a research proposal, and the names of three referees to A. K. Colter, Chairman, Department of Chemistry, University of Guelph, Guelph, Ontario, Canada, N1G 2WI. (1750)

#### ACADEMIC OPENING

The Department of Chemistry of Yale University is seeking applications for appointment to our faculty at the Assistant Professor level in inorganic chemistry. The appointment would become effective in the 1975-76 academic year. Expertise in x-ray crystallography is required; however, a research program in structural chemistry should complement a program in another subdiscipline, such as bioinorganic or organometallic chemistry.

Yale has an active Affirmative Action Program and we are especially interested in minority group or female candidates who meet the above criteria.

or female candidates who meet the above criteria.

Candidates should request referees to write and should send a curriculum vitae, a list of publications, brief summaries of predoctoral and any postdoctoral research, and a brief outline of proposed research projects to the Chairman, Department of Chemistry, Yale University, New Haven, Connecticut, 06520. Applications should be sent promptly, preferably by December 31, 1974 to assure consideration. (1773)

#### **IMPERIAL** COLLEGE

Applications are invited for a POSTDOCTORAL RESEARCH AS-SISTANT or POSTGRADUATE STUDENT, to develop light scattering techniques for determination of the size and refractive index of particles in flames. Applicants should have good qualifications, or have adequate experience, in light scattering and related fields.

Applications, including curricula vitae and the names of two referees, should be sent to Dr A. R. Jones, Department of Chemical Engineering and Chemical Technology, Imperial College, London SW7 2BY.

(1885)

#### UNIVERSITY OF BRISTOL DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH **ASSISTANTSHIP**

Applications are invited from candidates with research experience in protein chemistry and/or enzymology for a Postdoctoral Research Assistantship to work in collaboration with Dr J. Williams on an M.R.C. supported project involving a structural and functional investigation of metal-binding fragments from transferrin.

The appointment is available now for a period of up to three years at an initial salary up to £2,412 (plus benefit of Threshold Agreement supplement as appropriate).

Interested candidates should write to: Dr J. Williams, Molecular Enzymology Laboratory, Department of Biochemistry, University of Bristol, Medical School, Bristol BSS 1TD. (1784)

## **Analyst For Drug Metabolism**

Applications for this post are invited from scientists with experience of analytical methods and instrumentation applicable to Drug Metabolism studies. They should be able to develop new analytical methods, should be familiar with the techniques of spectrophotometry, fluorimetry, all types of chromatography and mass spectrometry, and should be able to subject their results to kinetic analysis. Preference will be given to candidates with some knowledge of the metabolic processess affecting non-endogenous compounds.

We are seeking someone with research experience but we will consider new graduates who have taken relevant degree courses.

We encourage publication of appropriate work. We have active links with a number of university departments, units of clinical pharmacology and physicians involved in drug trials.

Working conditions include a good career/salary structure, flexible working hours and a basic annual holiday of four weeks. Various attractive residential areas are within easy reach of the Research Institute and help may be provided with removal expenses where appropriate.

Please apply in writing with brief details of experience, salary etc., to the Personnel Manager, May & Baker Ltd., Dagenham, Essex or telephone for an application form to Mrs A. E. Jones on 01-592 3060 Extension 506. To help us please quote reference No. 260/N/1.

(1859)

#### **BOTSWANA**

## FISHERIES SUPERINTENDENT

Required to supervise staff in the Department of Agriculture engaged on the manufacture and maintenance of fisheries equipment, and to design special equipment for use in the Fisheries Section. He will also be involved on some development project work.

Candidates should have a Diploma in Fishery with at least 5 years' appropriate experience.

Salary will be in the scale £2,308 to £3,710 p.a. which includes an allowance, normally tax-free, currently in the scale £510 to £1,146. This allowance is under review, and a new scale ranging from £654 to £1,902 is expected to be approved shortly. Initial tour of two to three years.

Benefits include: 25% gratuity on basic salary, paid passage, education allowances, holiday visit passages, generous leave, accommodation at reasonable rental. A car loan up to £600 and an appointment grant up to £300 may also be payable.

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Ministry of Overseas Development.

For further particulars you should apply, giving brief details of experience to:

## crown age

M Division, 4 Millbank, London SW1P 3JD, quoting reference number MID/740816/NF (1876)

#### **BIOCHEMICAL TECHNICIAN**

Biochemical Technician required for small laboratory engaged in Metabolic Studies. Some experience with enzymes an advantage. Salary £1,800 to £2,800. Please apply with details of experience and names and addresses of two referees to: The Director, Alfred Chester Beatty Body Dynamics Laboratory, Bro Cranbrook, Kent TN17 3DT. Brooksden,

(1897)

#### UNIVERSITY OF MANCHESTER SENIOR LECTURER IN EXPERIMENTAL PATHOLOGY

EXPERIMENTAL PATHOLOGY

Applications are invited for this post in the Department of Pathology. The post involves teaching the principles of Pathology and research within a group investigating the immunological and migratory properties of lymphocytes. This group which is partly supported by an M.R.C. programme is concerned with the recognition structures on lymphocytes and endothelial cells which govern the migration of lymphocytes from the blood into the tissues. For this project experience of membrane fractionation techniques or glycoprotein chemistry would be relevant. A second project is concerned with the recognition of transplantation and other antigens by T cells. The post will not carry clinical duties. Salary range p.a.: £4,707 to £5,844. F.S.S.U. Further particulars and application forms (returnable by December 21) from the Registrar, The University, Manchester M13 9PL. Quote Ref. 229/74/N. (1809)

#### UNIVERSITY OF MANITOBA FACULTY OF MEDICINE

invites applications and nominations position of for the

#### PROFESSOR AND HEAD

#### DEPARTMENT OF BIOCHEMISTRY

DEPARTMENT OF BIOCHEMISTRY

Candidates should have a substantial record of accomplishment in Biochemical research as well as extensive teaching experience. The Department is responsible for the teaching of Biochemistry to medical students and also has an established graduate program leading to the Ph.D. degree. Applications and nominations should be accompanied by a curriculum vitae and submitted to:

Dr. Henry G. Friesen
Chairman: Biochemistry Search Committee
Department of Physiology
Faculty of Medicine
University of Manitoba
Winnipeg, Manitoba
R3E OW3, Canada (1861)

## Papua New Guinea

## Land Utilisation Officers

Applications are invited from graduates in agricultural science or science with a major in soil science for posts with the Department of Agriculture, Stock and Fisheries. Candidates should have good postgraduate experience and proven abilities detailed in either a) or b) below:-

a) Class 2. Experience in the conduct and successful completion of soil and land use surveys is essential. Appointees will be involved in reconnaissance surveys in the field or the collection and collation of data with

investigations into specialised fields of pedology, land use, soil physics and conservation.

b) Class 3. Working experience as a Pedologist with managerial and interpretative responsibilities in applied land use essential. Appointment will be made either to control a major regional soil survey unit and originate programmes for laboratory and field study or to be involved in reviving land utilisation patterns against a background of economic and technological advances.

#### Pay per annum

Expressed in \$A. Current rate of exchange A1.76 = £1.00 approx.

Class	Salary	Attraction Allowance	1960 2130	
2	4525	4570		
3	5525	4975		

Period of engagement is for two years (renewable in most instances). General entitlements are very attractive and include a

generous gratuity (approx. 25% of salary combined with attraction allowance), education allowance for dependent children attending school overseas, return air passages with personal effects and luggage allowance, low cost married and single accommodation, and generous leave conditions.

Please write or telephone immediately for an application form and full details of the posts. The Papua New Guinea Public Service Board Representative, 22 Garrick Street, London W.C.2. Telephone: 01-240 1780.

Papua New Guinea

#### DIRECTOR

Applications are invited for the position of DIREKTOR DES INSTITUTS FÜR TIERZUCHT UND TIERVERHALTEN FORSCHUNGSANSTALT FÜR LANDWIRTSCHAFT,

a federal research institution engaged in reproductive biology, animal behaviour and genetics. Staff of 250 including 16 scientists. Research budgeted, Facilities: 2,500 m<sup>2</sup> of laboratory space; 4 research farms (1200 ha); live stock of 1,200 cattle, 2,000 pigs, 1,000 sheep. Locations: main laboratories and 2 farms at Mariensee near Hannover; laboratory and 2 farms at Trenthorst near Lübeck.

Qualifications: Internationally established research reputation. Applicants with biochemical and physiological background should be enabled to coordinate the research programmes of the different restrons.

Salary: approx. 65,000 DM/annum (B 3 tenure position in government service).

To apply, send curriculum vitae, summary of research activities, list of publications and reprints before December 31, 1975 to:
Prof. Dr E. Zimmer
Präsident of
Forschungsanstalt für Landwirtschaft
Bundesaltes 50

Bundesallee 50 D 33 Braunschweig Federal Republic of Germany

(1792)

#### NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of

#### TIMBER RESEARCH OFFICER

Applicants must have a degree or equivalent pro-fessional qualification in timber or structural engineering and experience in the use of timber in the mining and other industries.

The timber research officer's duties will include making surveys of timber and forest products utilization by the Zambian industries including the mining industry, planning and executing applied research in the use of timber and forest products and liaising with industries on timber and forest products utilization.

Salary according to qualifications and experience

on the scales:— Senior Professional Officer K4,680 by 240 to K5,640 Principal Professional Officer
K5,840 by 240 to K6,800

Senior Principal Professional Officer
K7,000 by 200 to K7,600

There is a superannuation scheme for Zambians. Non-Zambians will be paid a graduated gratuity of 20% of the total carnings in the first year. 25% in the second year and 30% in the third year of resident service. Passages will be paid for the officer, wife and minor dependent children.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to:

The Secretary General,
National Council for Scientific Research,
P.O. Box CH 158,
Chelston, Lusaka,
Zambia. (1794)

#### NEWNHAM COLLEGE TRINITY COLLEGE, CAMBRIDGE

Women chemists are invited to apply for the post of LECTURER IN INORGANIC CHEMISTRY, tenable as from October 1, 1975. Salary on pensionable scale for Cambridge University Assistant Lecturers and Lecturers: £2,393 per annum by varying annual increments to £5,402 per annum. The appointment is a joint one and will carry a Fellowship at Newnham College and a Lectureship at Trinity College. Research opportunities in the University Department of Chemistry. Further particulars may be obtained from the Principal, Newnham College. The closing date for the receipt of applications is December 31, 1974. (1854)

#### NEWNHAM COLLEGE, CAMBRIDGE

Women physicists are invited to apply for the post of LECTURER IN PHYSICS, tenable as from October 1, 1975. Salary on pensionable scale for Cambridge University Assistant Lecturers and Lecturers: £2,393 per annum by varying annual increments to £5,402 per annum. Research opportunities in the Cambridge University Department of Physics. Further particulars may be obtained from the Principal. The closing date for the receipt of applications is December 31, 1974. (1855)

#### BIOCHIMICA ET BIOPHYSICA ACTA

Applications are invited for the post of

### **EDITORIAL SECRETARY**

The BBA Editorial Secretariat, located in Amsterdam, is a small team of biochemists involved in the selection of manuscripts for publication in the world's largest biochemical journal. The work involves the choosing of reviewers for submitted articles, and subsequent correspondence with authors and editors, leading to eventual acceptance or rejection of the manuscripts. The Secretariat also maintains close contact with the journal sub-editing team, and advises on matters such as nomenclature and terminology. They thus play a central role in the quality control of the journal.

Candidates should meet the following requirements:

A wide knowledge of biochemical sciences

2-4 years of post-graduate research experience, preferably to PhD. or M.Sc. level

Initiative, decisiveness, tact and an eye for detail

An excellent command of the English language

Age under 30 and resident in Europe.

The salary for this position starts from 2,000 Dutch guilders per month depending on age and experience.

Holidays amount to 22 working days plus public holidays per year.

Applications, including curriculum vitae, should be addressed to:

The Personnel Department, Associated Scientific Publishers, P.O. Box 2400, AMSTERDAM, The Netherlands.

Further details are available on request.

(1872)

## NEW ZEALAND

Department of Scientific & Industrial Research

## SCIENTIST

#### IONOSPHERIC RESEARCH

A vacancy exists in the lonosphere Section of the Physics and Engineering Laboratory, D.S.I.R., Lower Hutt, New Zealand, for a Scientist to undertake research in electromagnetic theory with application to ionospheric radio propagation. The research programme includes investigation of radio propagation and antenna problems within New Zealand and studies of the ionosphere and magnetosphere using radio and other techniques.

Applicants should have a Ph.D. or Honours Degree in Physics or Engineering, with relevant experience.

A salary of up to \$11,153 per annum is payable, according to qualifications and experience. Further information may be obtained from the Director, Physics and Engineering Laboratory, Private Bag, Lower Hutt, New Zealand.

#### PASSAGES:

Fares for appointee and his wife and family, will be paid.

#### INCIDENTAL EXPENSES:

Up to \$120 for a single man and \$800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London SW1Y 4TQ, with whom applications will close on January 5, 1975

Please quote reference PT 136 when enquiring.

University.
Closing Date: December 7, 1974.
The University reserves the right to make no appointment or to appoint by invitation. (1868)

#### UNIVERSITY OF AUCKLAND New Zealand

Applications are invited for the following appointments:

#### LECTURESHIP IN CIVIL **ENGINEERING**

Applicants should have an Honours degree or its equivalent. Although not essential, professional experience is desired. Opportunities are available for the pursuit of a higher degree.

#### SENIOR LECTURESHIP/ LECTURESHIP IN ELECTRICAL ENGINEERING

Well-qualified applicants in any field of electrical engineering will be welcomed, but, preference will be given to applicants with teaching and research experience in electromagnetic fields and radio antennae, or in control systems; possession of a higher degree and industrial experience would be advantageous advantageous

#### LECTURESHIP IN MECHANICAL ENGINEERING

Applicants should have qualifications and experience in one of the following special areas—Control engineering; Dynamics; Industrial thermo-

Control engineering; Dynamics; inquisition dynamics.

Salary scales: Commencing salary within the appropriate scale will be determined in accordance with qualifications and experience. Senior Lecturer NZ59.503 to NZ511,153. In exceptional cases the Council may extend this scale up to NZ512,142.

Additional information, conditions of appointment and application procedure is obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH OPF.

Applications, close on December 7, 1974.

(1866)

#### GEOGRAPHY GRADUATE

(female) required for administrative work and occasional teaching duties. Salary according to age and experience on the scale £1,055 & £1,646, plus full residential benefits. Please write to F. J. Bingley (Warden and Director of Studies), Flatford Mill Field Centre, East Bergholt, nr. Colchester, CO7 6UL. (1873)

### **Senior Pharmacologist Anti-Inflammatory Research**

Applications are invited for a senior post in our Pharmacology Department in Welwyn Garden City, Hertfordshire. The department is responsible for carrying our research and screening work aimed at the development of new drugs in which the pharmacologists participate in the research programmes of interdisciplinary groups.

The senior pharmacologist we appoint will be responsible for directing the work of a team of pharmacologists engaged in anti-inflammatory research. Applicants should have a Ph.D. qualification and preferably some post-doctoral experience in anti-inflammatory research.

Our Pharmacology Department is located in new laboratories where the facilities and working conditions are excellent. Conditions of service are above average and in appropriate cases generous assistance with relocation will be available.

Roche Products Limited is part of a major international pharmaceutical firm based in Switzerland and is itself one of the leaders in the industry in the United Kingdom. If you would like to apply for this post please write for further information, a Company booklet, to the Welwyn Personnel Manager.

Closing date for applications, December 13, 1974.

Box 278, Zomba, Malawi, Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P ODT. Further particulars may be obtained from either address." (1878)

#### UNIVERSITY OF DAR ES SALAAM TANZANIA

Applications are invited for the following posts in the DEPARTMENT OF SOIL SCIENCE AND AGRICULTURAL CHEMISTRY:

#### PROFESSOR OF SOIL SCIENCE

Applicants should have a Ph.D., or equivalent research experience, in any ONE of the following: Soil Physics; Soil Chemistry; Soil Fertility; Plant Nutrition; Pedology. Previous university teaching experience is desirable but not essential.

#### SENIOR LECTURER/LECTURER IN BIOCHEMISTRY (Agriculture)

Applicants should have a Ph.D. in Biochemistry or equivalent research experience. Preference will be given to those whose first degree is in Chemistry rather than in Agriculture, Appoince will be required to teach Biochemistry and some related aspects of Physical Chemistry to undergraduates, studying for the B.Sc.(Agric.) and B.Sc.(Forestry). He will be expected to conduct research and direct postgraduate studies in Biochemistry.

Salary scales Professor T£3,332 to T£3,662 p.a. Senior Lecturer T£2,632 to T£3,052 p.a. Lecturer T£2,150 to T£2,570 p.a. (T£1=£1,19 sterling). The British Government may supplement salaries in range £996 to £2,448 p.a. (sterling) for married appointees or £348 to £1,500 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. F.S.S.U. Family passages; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not Jater than December 11, 1974 to the Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London WIP ODT. Further particulars may be obtained from either address.

#### UNIVERSITY OF DAR ES SALAAM TANZANIA

Applications are invited for the post of

#### PROFESSOR IN MATHEMATICS

PROFESSOR IN MATHEMATICS

Applicants must hold a doctorate. Appointee should have experience over a wide range of Mathematics and its applications, and he should be strongly interested in the development and encouragement of Mathematical curricula at all levels relevant to a rapidly developing country. Salary scale: T£3,332 to T£3,662 p.a. (T£1=£1.19 sterling). The British Government may supplement salary by £2,448 p.a. (sterling) for married appointee or £1,500 p.a. (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. F.S.S.U. Family passages; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than December 11, 1974 to the Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania. Applicants resident in U.K. should also send I copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (1881)

## CSIRO

#### **AUSTRALIA**

## DIVISION OF COMPUTING RESEARCH

CANBERRA, A.C.T.

## RESEARCH **SCIENTIST**

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists-located in Divisions and Sections throughout Australia.

FIELD:

## **PICTURE PROCESSING**

GENERAL: The Division of Computing Research, with headquarters in Canberra, A.C.T., operates a computer system based on a CDC Cyber 76 computer. An expanding network of mini-computers at CSIRO research centres enables the concentration of interactive and batch work in Canberra. Currently about thirty batch terminals and more than one hundred and fifty interactive terminals are connected.

The capacity and potential of the computer system provide an excellent tool for research and development projects. Research studies at present include picture processing, simulation techniques, operating systems, computer languages and data-base management.

Additional facilities for processing pictures on the computer system are being acquired. In particular, an image-dissector scanner and a terminal for displaying grey-scale images will be interfaced to the system in Canberra. This equipment will be used to develop picture processing software for a variety of applications and will assist current research on the evaluation of techniques for picture interpretation and machine perception.

DUTIES: To conduct research on techniques for picture processing and to participate in the development of associated facilities.

QUALIFICATIONS: A Ph.D. degree in an appropriate field or equivalent qualifications together with demonstrable research ability.

SALARY: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A10,778 to \$A16,187 p.a.

TENURE: The position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 900/261, should reach:-

The Personnel Officer, Australian Scientific Liaison Office, 64-78 Kingsway, LONDON WC2B 6BD

by the 13th December, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(1930)

#### CSIRO

#### **AUSTRALIA**

#### DIVISION OF APPLIED **GEOMECHANICS**

SYNDAL, VIC.

## RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees-2,100 of whom are research and professional scientists-located in Divisions and Sections throughout Australia.

#### FIELD:

## COASTAL AND OCEAN ENGINEERING

GENERAL: The Division of Applied Geomechanics undertakes a wide range of studies in rock mechanics and soil mechanics. An expansion of the Division's programme of coastal investigations is currently under way to meet the substantial expansion of industrial, offshore mining and other engineering activities which can be foreshadowed along the Australian coastline and offshore on the Australian continental shelf.

DUTIES: To join a research team to study and categorise the physical problems of the Australian coast and continental shelf, and to formulate basic multidisciplinary research projects to facilitate future engineering developments in the application of geomechanics.

QUALIFICATIONS: A Ph.D. degree or equivalent qualification in the engineering field, together with demonstrable research ability and an adequate understanding of the physical branches of marine science and an appreciation of the complex ecology of coastal and continental shelf areas.

SALARY: Appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A10,778 to \$A16,187 p.a. Consideration will be given to appointment at a higher level for an outstanding applicant.

TENURE: Either an indefinite or a fixed term appointment may be negotiated. Indefinite appointments carry Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 920/188, should reach:-

The Personnel Officer. Australian Scientific Liaison Office, 64-78 Kingsway, LONDON WC2B 6BD

by the 13th December, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(1931)

#### **TECHNICIAN**

for work on the effects of carcinogens on protein and nucleic acid metabolism. Salary on Whitley Council scale (£1,986 to £2,445 including London Weighting) depending on experience. Applications in writing giving details of experience, qualifications and names of two referees to The Director (N), Courtauld Institute of Biochemistry, The Middlesex Hospital Medical School, London WIP 5PR. (1882)

#### UNIVERSITY COLLEGE LONDON DEPARTMENT OF BIOPHYSICS ELECTRON-MICROSCOPIST

RESEARCH ASSISTANT required to work with Professor R. Miledi on problems in Neurobiology, which forms part of a long-term Project supported by the M.R.C.

Preference given to applicants with experience of freeze-etching or analytical electron-microscopy. Salary within Lecturer scale plus London Allow-

Applications with curriculum vitae and names and addresses of two referees to Mrs K. Garnons-Williams, Biophysics Dept. (N), University College London, Gower Street, London WCIE 6BT. (1883)

#### THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London)

COURTAULD INSTITUTE OF BIOCHEMISTRY Applications are invited for a Research Assistant post in the Steroid Unit of the Institute. Candidates should be at Doctorate level with a sound basis in Chemistry and Biochemistry. Salary according to age and experience within the range £2,931 to £3,285 plus London allowance, currently £213 per annum and superannuation under F.S.S.U. Applications giving details of academic achievement and the names and addresses of two referees to the Director, Courtauld Institute of Biochemistry, The Middlessex Hospital Medical School, London W1P 5PR, by December 2, 1974 quoting (C.R.C. Biochem 31).

#### THE HORMEL INSTITUTE OF THE UNIVERSITY OF MINNESOTA

invites applications from qualified individuals for the position of EXECUTIVE DIRECTOR of The Hormel Institute which is located in Austin, Minnesota. The Executive Director is responsible for overall administration of an institute with 80-90 employees, including 20 of whom have academic rank. Candidates for this position should be recognised authorities in the lipid field, and should have at least 12 years of research experience in the field. The director is expected to maintain an active research programme.

Closing date for receipt of all materials is February 1, 1975. Send curriculum vitae, a list of publications and names of three referees to Dr J. E. Gander (Chairman, Search Committee), Department of Biochemistry, University of Minnesota, St Paul, MN 55108. (1886)

#### **QUEENS COLLEGE** OF THE CITY UNIVERSITY OF NEW YORK ASSISTANT PROFESSOR

position available for 1975/76 academic year, with possibility of reappointment. Ph.D. required. Send curriculum vitae to Chairman, Dept of Earth and Environmental Sciences, Queens College, Flushing, New York 11367. An Affirmative Action/Equal Opportunity Employer. (1888)

#### THE DEPARTMENT OF BIOLOGICAL SCIENCES

of the

#### UNIVERSITY OF SOUTHERN **CALIFORNIA**

has three vacancies in Ecology and Evolution. One is in the area of marine ecosystems, especially modelling and mathematical ecology. One is for a marine population ecologist with major interest in phytoplankton. The third full-aime faculty position offered in conjunction with the Allan Hancock Foundation is for an Evolutionary biologist with interest in a major invertebrate marine group. The position involves some responsibility for the Foundation's research collection, and applications are encouraged with interest in biochemical evolution. Send curriculum vitae to Dr Bernard C. Abbott, University of Southern California, Los Angeles, CA 9007, U.S.A. An Equal Opportunity/Affirmative Action Employer. (1889)

#### ROYAL POSTGRADUATE MEDICAL SCHOOL

TECHNICAL OFFICER (2 posts) required for Department of Clinical Pharmacology to join groups working on

- (1) The role of catechol amines in essential hypertension and
- The pharmacology and metabolism of new drugs in man.

Salary on scale £2,268 to £3,729 per annum plus threshold payment, according to age and experience.

Applications to the Personnel Officer (743 2030 Ext. 93), R.P.M.S., Hammersmith Hospital, DuCane Road, London W12 0HS, quoting ref. o. 20/(1) or (2).

#### UNIVERSITY OF NEWCASTLE UPON TYNE

NORTHERN COKE RESEARCH LABORATORY

RESEARCH LABORATORY

Applications are invited for a post of Senior Research Associate (from £2,580) or Research Associate (from £2,118) in the Laboratory for research on fundamental problems connected with the strength of coke and its dependence on its precursors and mode of formation. The Laboratory is within the School of Chemistry and the post is suitable for any candidate interested in Material Science, irrespective of initial degree. It is available until September 30, 1976 in the first instance, commencing January 1, 1975, or by arrangement. Starting salary according to age and experience.

Applications including a brief curriculum with

Applications including a brief curriculum vitae and the names of two referees should be sent as soon as possible to the Honorary Director, Professor D. H. Whiffen, School of Chemistry University of Newcastle upon Tyne, Newcastle upon Tyne, NEI 7RU. (1895)

#### ORGANIC CHEMIST (post Ph.D.)

required for work in synthesising steroid and other derivatives for use as immunogens and for labelling with radioiodine for use in Radioimmunoassay systems. Interest in microanalytical work and in medical application desirable.

Appointment for three years on salary scale £2,019 to £3,636 per annum.

Applications, including the names of tw referees, to Dr. W. M. Hunter, Head, M.R.C. Radioimmunoassay Team, 2 Forrest Road, Ediburgh EH1 2QW. (1899)

#### NUFFIELD INSTITUTE FOR MEDICAL RESEARCH

A vacancy has arisen for a postgraduate student to work on electromagnetic flowmeter development for a period of up to 3 years. Candidates must be British subjects and have either a first class or upper second class degree in Physics or Engineering. Apply to Dr. D. G. Wyatt, Headley Way, Headington, Oxford. (1900)

#### UNIVERSITY OF BRISTOL M.R.C. BRAIN AND PERCEPTION LABORATORY

#### POSTDOCTORAL RESEARCH **ASSISTANTSHIP**

for experimental work in human perception.

We are looking for candidates with initiative and originality. The area of research extends from cognitive processes to neurological disturbances, including development of novel experimental techniques.

Commencing salary up to £3,108 per annum (plus any Threshold Agreement payments applicable) according to age and experience.

Applicants should write in confidence to Professor R. L. Gregory, Brain and Perception Laboratory, Department of Anatomy, The Medical School, University Walk, Bristol BS8

Applications are invited from biology graduates for a three year post as

#### RESEARCH ASSISTANT

initially in the Pathology Department of St. George's Hospital Medical School, and thereafter at the Middlesex Hospital Medical School. The successful candidate will participate in projects using immuno-fluorescent and chemical techniques and scanning electron microscopy. Previous laboratory experience desirable. Starting salary in the region of £1,600 p.a. depending on qualifications.

Apply to Dr N. Woolf, Pathology Department, St. George's Hospital Medical School, Hyde Park Corner, London, SW1X 7NA. (1909)

#### **AUSTRALIA**

DIVISION OF WILDLIFE RESEARCH CANBERRA, A.C.T.

## **SENIOR BIOLOGIST**

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees-2,100 of whom are research and professional scientists-located in Divisions and Sections throughout Australia.

FIELD:

## **MARSUPIAL** PHYSIOLOGY

GENERAL: The Division of Wildlife Research includes some forty scientists engaged in research on biology of native and introduced birds and mammals. Its principal interests at present are in ecology and behaviour but also include parasitology and physiology.

The Division is now increasing the component of physiology in its programme and is seeking an animal physiologist to develop this work.

DUTIES: To lead the group of physiologists that is being established and to integrate their work with the ecological and other investigations.

QUALIFICATIONS: Applicants should have an outstanding record in research in marsupial physiology, preferably in either reproduction or metabolism as it is anticipated that these fields will be of major importance in the Division's total programme.

SALARY: Appointment will be made within the salary ranges of Senior Principal Research Scientist or Chief Research Scientists: \$A20,359 to \$A22,482 p.a.

TENURE: The position is available for an indefinite period and Australian Government Superannuation benefits are available. Alternatively a fixed term appointment may be negotiated.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 560/342, should reach:-

The Personnel Officer, Australian Scientific Liaison Office, 64-78 Kingsway, LONDON WC2B 6BD

by the 13th December, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

HIGHETT, VIC.

## RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees-2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD:

## **SOLAR ENERGY** UTILIZATION

GENERAL: The Division of Mechanical Engineering is seeking a Research Scientist to take part in the activities of the solar energy utilisation group, For a number of years the Division has conducted research in this area and current investigations include the use of solar energy as a source of heating for domestic and commercial hot water, space heating and cooling, and industrial process heating. The work involves theoretical studies, prototype development and experiments under laboratory and field conditions.

The Division also conducts extensive research in the fields of heat and mass transfer, air conditioning, environmental control and fluid dynamics.

DUTIES: To conduct research into methods of utilising solar energy as a source of heat at temperatures up to 120°C and to lead small teams oriented to specific goals within this area.

QUALIFICATIONS: A Ph.D. degree in mechanical engineering or equivalent qualifications and demonstrable research ability, preferably with appropriate postdoctoral experience. An understanding of computer simulation techniques is desirable and some background in solar energy utilisation would be an advantage.

**SALARY:** The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A10,778 to \$A16,187 p.a.

TENURE: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 430/337, should reach:-

The Personnel Officer. Australian Scientific Liaison Office. 64-68 Kingsway. LONDON WC2B 6BD

by the 13th December, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(1933)

#### UNIVERSITY OF WESTERN AUSTRALIA Perth

Applications are invited for appointment to a CHAIR IN CIVIL ENGINEERING.

CHAIR IN CIVIL ENGINEERING.

This is one of two Chairs in the Department of Civil Engineering, the other being held by the current head, Professor D. H. Clyde. The Department is one of three in the Faculty of Engineering, the other two being Electrical and Electronic Engineering and Mechanical Engineering, Preference will be given to applicants with special interests in the water or the geotechnical fields, but applications will be considered from all candidates who, if appointed, would make major contributions to the University and the community through their specialities. Detailed information on the teaching and research activities of the Department and conditions of appointment may be obtained from the Staffing Officer.

The headship of University departments, in particular the tenure of headships, is at present under review and it is likely that these will become fixed term appointments from within departments.

The current salary for a Professor is SA19,614 p.a. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme.

Applications in duplicate stating full personal particulars, qualifications, experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009, by December 14, 1974.

Further particulars and conditions of appointment available from Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WCIH OPF. This is one of two Chairs in the Department

#### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)
KEPPEL STREET, WC1E 7HT

WINCHES FARM FIELD STATION, ST. ALBANS

A Senior Laboratory Technician is required to work at St. Albans on a project on the immunology of schistosomiasis, in collaboration with parasitologists investigating vaccination against this disease.

this disease.

Candidates should preferably be graduates or hold F.I.M.L.T./H.N.D. and have experience of immunological work. Salary, depending on qualification and experience, in the range £2,238 to £2,835 plus threshold payments.

Applications in writing, giving details of career etc., to Secretary (A1) N at the London address by December 21, 1974. Further information may be obtained from Dr. M. G. Taylor (St. Albans 53858).

#### UNIVERSITY OF HONG KONG LECTURESHIP/ASSISTANT LECTURESHIP IN BIOCHEMISTRY

Applications are invited for a post of Lecturer/ Assistant Lecturer in Biochemistry. An interest in Molecular Genetics or experience in immuno-logical methods would be an advantage but neither is regarded as essential.

Annual salaries (currently under review and superannuable) are:— Lecturer: HK\$44,040 by 2,940 to 49,920 BAR 52,860 by 2,940 to 61,680 by 3,000 to 73,680; Assistant Lecturer: HK\$32,280 by 2,940 to 41,100. At the time of issue the rate of exchange is £1=HK\$12.00 approx.

The entry point to the salary scale will depend on qualifications and experience: for example, a medically-qualified appointee who has completed his pre-registration year will be appointed as a Lecturer at the minimum point. Salaries for female appointees below HK\$67,680 are slightly lower than given above; equalization of male and female salary scales will be achieved by April 1, 1975.

Candidates who applied earlier in the year will be reconsidered and need not apply again but may submit further material in support of their applications if they wish.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts.), 36. Gordon Square, London WCIH OPF, or the Secretary to the Council, University of Hong Kong.

Closing date for applications is December 20, 1974. (1907)

#### UNIVERSITY OF EAST ANGLIA LECTURERS IN BIOLOGY **ECOLOGY AND** DEVELOPMENTAL BIOLOGY

Applications are invited for appointments as LECTURER in the School of Biological Sciences to begin not later than September 1, 1975, in the fields of ecology and developmental biology. Salary within the range £2,118 to £2,757 on the scale £2,118 to £4,896, plus threshold payments and F.S.S.U.

Details from the Establishment Officer, University of East Anglia, Norwich NR4 7TJ, with whom applications (one copy only) together with the names and addresses of three persons to whom reference may be made, should be lodged not later than December 9, 1974. (1913)

#### **GRIFFITH UNIVERSITY** BRISBANE, AUSTRALIA SCHOOL OF SCIENCE

In the early years the main areas of concentration of the School will be experimental physics, chemistry, and biochemistry. Applicants for posts 1 and 2 should be prepared to be associated with interdisciplinary research projects in one or more of these areas, as well as pursuing their own research interests. Applications are invited from men and women for the positions described below to be available for appointment, in the case of posts 1 and 2, on or about September 1, 1975, in the case of post 3 on or about January 1, 1975.

1. LECTURESHIP—BIOLOGICAL ORGANIC CHEMISTRY: The appointee's initial teaching responsibilities will be in the planning of the second year chemistry courses, both theoretical and practical. Candidates should have research experience in some biological aspect of organic chemistry

experience in some biological aspect of organic chemistry.

2. LECTURESHIP—APPLIED | MATHEMATICS: (Theoretical Biologist/Chemist/Physicist): Applicants must have strong mathematical expertise and an interest in scientific problems. Preference may be given to applicants with a research interest in biological problems, but this is not a requirement. The initial teaching responsibility of the appointee would be in teaching mathematics for second year science students.

3. RESEARCH FELLOWSHIP — ORGANIC CHEMISTRY: A post-doctoral research fellowship is available, for one year in the first instance, for work on "Co-polymers of Sucrose Derivatives", funded by the International Sugar Research Foundation, and under the general direction of Professor R. D. Guthrie. Applicants should have experience in synthetic organic chemistry, or in polymer chemistry.

Salaries: Lecturer SA9,002 to \$12,352; Research Fellow \$A7,454 to \$7,837.

Further details and the method of application for nosts 1 and 2 for which the closing date is

Further details and the method of application for posts 1 and 2, for which the closing date is **December 2**, 1974, can be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WCIH 0PF.

Applications for post 3 should be made, as soon as possible, directly to Professor R. D. Guthrie, School of Science, Criffith University, Nathan, Brisbane, Quensland, Australia 4111, and should contain the names of two referees.

#### QUEEN ELIZABETH COLLEGE (UNIVERSITY OF LONDON) CAMPDEN HILL ROAD, W8 7AH TEMPORARY RESEARCH POST

Chemist/Biochemist required in Microbiology Department, January to September 1975 to assist in a isolation of serum protein growth factor required by human cells in culture. Salary at rate of £1,761 p.a. plus threshold payments.

Apply to Professor S. J. Pirt. (1922)

#### THE POLYTECHNIC WOLVERHAMPTON

#### DEPARTMENT OF BIOLOGICAL SCIENCES LABORATORY TECHNICIANS

(3 posts)

Preference will be given to candidates with interests in one of the following subject areas:—Biochemistry, Plant. or Animal Physiology and Plant Pathology or Microbiology. Duties would involve the servicing of laboratories for undergraduate practical classes.

Salary on Scale Grade T1 £807 to £1,866 commencing point dependent upon age and experience. Additions to scale for current threshold allowances and recognised qualification.

Application form and details from:—

The Establishment Officer

The Polytechnic

(1923)

#### GRADUATE BIOCHEMIST

required by Dept. of Experimental Pathology twork on immunochemical and electron microscopis studies in glomerulonephritis. Apply, with detail of experience and names and addresses of two referees to, The Secretary, St. Mary's Hospita Medical School, Paddington, London W2 IPG Ref. EPBG. (1943)

#### THE ROYAL DENTAL HOSPITAL OF LONDON

SCHOOL OF DENTAL SURGERY (University of London) 32 Leicester Square, W.C.2.

32 Leicester Square, W.C.2.

Applications are invited for the appointment of Graduate Research Assistant in the Department of Physical Sciences on either a full-time or part-time basis. Applicants must hold a good degree in Physics, Chemistry or a related subject but previous research experience is not essential. In the case of a full time appointment, the possibility of extension and would permit registration for a higher degree as a part-time internal student of the University of London. Salary range, according to age and experience, from £1,606 to £1,902 plus London Allowance at £213 p.a. and Threshold Agreement Payments and F.S.S.U. benefits.

Further particulars may be obtained from Dr. N. E. Waters and applications should be sent to the School Secretary. (1944)

Applications are invited from suitably qualified personnel for the following vacancy in the Technical Services Department of Mount Isa Mines Limited.

### RESEARCH CHEMIST

#### **Location: Mount Isa** Queensland, AUSTRALIA

Ref. 9274

The successful applicant will be appointed to the X-ray analysis group in the chemical laboratory. The laboratory is equipped with a Philips PW1212 sequential spectrometer, two Philips PW1270 simultaneous spectrometers and a PDP-11 computer. The appointee will be required to maintain the quality of routine analyses on a continuous 24 hour basis and to expand and improve existing product/element calibrations and will also be required to assist in and interest and the product which the product is sufficient to the product that the product which the product is sufficient to the product that the product the product the product that in, and initiate, development work which may include investigations into sample and specimen preparation techniques, new calibration methods, mathematical projects and computer programming.

QUALIFICATIONS AND EXPERIENCE: Applicants must possess a degree or diploma in science and have a minimum of four years' practical industrial experience. Prior experience in X-ray analysis is essential.

REMUNERATION: Will depend on qualifications and experience. However, on commencement total remuneration including bonus, prosperity and annual leave loadings, production payment and holiday air fares is envisaged to be in the vicinity of \$A10,000 to \$A11,500 per annum. Salaries are reviewed annually and Zone "A" taxation

#### **GENERAL CONDITIONS:**

- · Married and single accommodation available.
- Assistance will be given with fares and removal expenses.
- · Six weeks and two days' annual leave and liberal sick leave with
- · Refund of medical expenses.
- · Immediate participation in superannuation plan.
- · Credit union facilities are available for new employees.

Applications should be addressed to Mr. T. B. A. Roberts

#### UNIVERSITY OF BRISTOL DEPARTMENT OF PATHOLOGY

#### REPRODUCTIVE IMMUNOLOGY GROUP

#### POST-DOCTORAL RESEARCH ASSISTANT/ASSOCIATE

Applications are invited for a further post within an established research group investigating immunological aspects of reproduction and development in laboratory rodents. Candidates should possess previous experience in immunology, developmental biology or reproductive physiology. Opportunities exist for a limited amount of teaching.

The post is available for up to 3 years in the first instance, with a salary on the scale £2,118 to £3,285, depending upon qualifications and experience, F.S.S.U. subject to accord of academic status. Starting date negotiable, but preferably within the next three months.

Applications (2 copies) should include full details of qualifications and experience, and the names of two referees, and be submitted to Dr. W. D. Billington, Department of Pathology, University Walk, Bristol BS8 1TD, as soon as possible. (1919)

#### UNIVERSITY COLLEGE CARDIFF

Applications are invited for the following post: RESEARCH ASSISTANT (Temporary) in the ZOOLOGY Department.

Salary Scale: £1,500 to £1,662. Duties to commence December 1, 1974 to March 31, 1976.

Applicants for the above post will be required to take part in a survey of faunal distribution in the Severn Estuary. The work involves collecting, using a light hovercraft, and laboratory analysis of samples. Applicants should be graduates with some zoological training and familiarity with two-stroke engines would be an advantage.

Applications, together with the names and addresses of two referees, should be forwarded to the Registrar, University College Cardiff, P.O. Box 78, Cardiff CF1 1XL by November 29, 1974. Please quote 0689. (1920)

#### UNIVERSITY OF BRISTOL DEPARTMENT OF PATHOLOGY

#### IMMUNOLOGY TECHNICIAN GRADE 4 OR 5

A vacancy exists within a research group investigating the immunological aspects of pregnancy for a Technician to take charge of the preparation and analysis of antisera and to participate in the various ongoing research projects. The person appointed will be the senior technician in the group, and will have responsibilities for the day-to-day running of the laboratories and the general supervision of other technical staff. Preference may be given to candidates with previous experience in column chromatography and electrophoresis, and ability to handle laboratory rodents is desirable. Initial salary on the scale £1,848 to £2,163 or £2,007 to £2,382, plus threshold payments under current arrangements (a revised scale is currently under review).

Applications with full details and the names of two referees to Dr. W. D. Billington, Department of Pathology, University Walk, Bristol BS8 ITD.

#### MERSEYSIDE COUNTY MUSEUMS

#### KEEPER (PHYSICAL SCIENCES) £3,573 to £3,939 p.a.

(plus threshold payment of £167.04)

Applications are invited for this post heading a new department concerned primarily with Astronomy, Space Technology and a Planetarium but which is expected to expand into other aspects of Physical Sciences.

Candidates should normally be science or engineering graduates with relevant research experience. Possession of the Diploma of the Museums Association would be an advantage.

Further particulars and application forms, returnable by November 29, 1974, are available from the Director (Dept 4), Merseyside County Museums, William Brown Street, Liverpool L3 8EN (Tel: 051-207 0001). (1939)

### SANDWELL AREA HEALTH AUTHORITY

#### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (University of London) Keppel Street, WC1E 7HT POSTDOCTORAL IMMUNOLOGIST WINCHES FARM FIELD STATION, ST. ALBANS

Applications are invited for an appointment, which will be for three years initially, to work on a project on the immunology of schistosomiasis, in collaboration with parasitologists investigating vaccination against this disease. The successful candidate will be in charge of newly-equipped laboratories at St. Albans, and will be assisted by a schior technician. Initial salary within the range £2,118 to £3,108, depending on experience and qualifications, plus threshold payments.

Applications, consisting of curriculum vitae and naming two referees, should be sent to Dr. G. Webbe, at the School's London address, by December 6, 1974. Further information may be obtained from Dr. M. G. Taylor (St. Albans 53858).

#### EDITORIAL ASSISTANTS

Recent graduates in Microbiology or allied subject required to work on Microbiology Abstracts and Virology Abstracts. Duties include proof reading, abstracting and some editing. Please apply in writing to Dr E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London WIV 5FG. Quoting Ref. No. (1925)

#### UNIVERSITY OF ADELAIDE WAITE AGRICULTURAL RESEARCH INSTITUTE WAITE PROFESSOR OF AGRONOMY

WAITE PROFESSOR OF AGRONOMY

Applications are invited for the above-mentioned appointment. The post was previously occupied, as the Waite Chair of Agriculture, by Professor C. M. Donald, F.A.A., who retired in March 1973. It has remained vacant pending the appointment of the new Director of the Institute, Professor J. P. Quirk, F.A.A.

The Professor will be Chairman of the Department of Agronomy for an initial period of three years, when the chairmanship will be reviewed, Applications are invited from persons active in the field of Agronomy or cognate disciplines. At present the major interests in the Department are in the fields of crop and pasture ecology and plant breeding. Information about the research and teaching of the Department of Agronomy is given in the Statement referred to below.

SALARY: SA19,614 a year with superannuation on the F.S.S.U. basis and, for an eligible candidate, supplementary superannuation and pension schemes.

FURTHER INFORMATION: Potential can-

clidate, supplementary superamacion and pension schemes.

FURTHER INFORMATION: Potential candidates are invited to obtain from the Secretary General, Association of Comomnwealth Universities (Appts), 36 Gordon Square, London WCIH OPF, or from the Registrar of the University, a Statement of Agronomy, the Waite Institute and the University, as well as the formal terms of appointment. Any further information desired about the conditions of appointment or the University generally should be sought from the Registrar; further information about research work, facilities, etc. in the Department or the Waite Institute may be sought from the Director of the Institute.

of the Institute.

APPLICATIONS (in duplicate) giving the particulars listed in paragraph 7 of the Statement should reach the Registrar of the University, G.P.O. Box 498, Adelaide, South Australia 5001, not later than January 31, 1975. (1936)

#### MASSEY UNIVERSITY Palmerston North, New Zealand LECTURER IN GENETICS

Applications are invited for the above-mentioned position in the Department of Microbiology and Genetics; the department is responsible for courses leading to the B.Sc., B.Sc.(Hons), M.Sc. and Ph.D. degrees. The successful applicant will assist in the continuing development of Genetics as an area of teaching and research and will participate in the offering of an introductory course in cell biology to first year students. Applicants who have experience in tissue culture studies and interests in cytogenetics and aspects of cell structure and function will be given favourable consideration.

Salary: NZS7,361 to NZ\$9,339.

Further details of this position and of the University, together with general conditions of appointment may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or from the Registrar of the University.

Applications close on January 15, 1975.

#### UNIVERSITY OF TROMSØ NORTH NORWAY FISHERY BIOLOGY RESEARCH GROUP

Applications are invited for the following positions:

#### TWO PROFESSORSHIPS AND ONE LECTURESHIP

ONE PROFESSORSHIP in Fisheries Biology for candidates with appropriate qualifica-tions and experience in the fields of Population Dynamics and/or Systems modelling. Duties will include development of courses and teaching of fishery students in these topics plus research in an integrated programme of fjord fish populations and their

ONE PROFESSORSHIP AND ONE LECTURESHIP IN AQUACULTURE. There is much interest in aquacultural developments and possibilities in North Norway, in which the successful candidate will have ample opportunity to participate. It is expected that those who are appointed contribute to the fjord research programme. Though experience in aquacultural techniques is required it is also hoped that the persons appointed will have a broad biological experience so that in both teaching and research he will be able to stress the more fundamental aspects of this subject.

The University is now considering long-range plans for expansion of its teaching and research capability in Fisheries Biology. A major programme of fishery and environmental research of fjords is being developed by a group of biologists headed by Professor A. H. Weatherley. Other fishery research programmes are being planned.

weatheriey. Other inshery research programmes are being planned.

Tromso is situated in a very large northern commercial fishing region and fishery biology is one of the areas of study being emphasised in the development of the University. The work of the fishery group is being conducted in conjunction with marine biologists, and fishery biology will be offered at both undergraduate and graduate levels. English may be used for teaching until Norwegian is learned.

The University is new and expanding rapidly, and those who obtain posts will be expected to participate in planning activities. The fishery group is part of the Institute of Biology and Geology and is housed in a new building well equipped for various kinds of teaching and research.

A new highly sophisticated 112 foot fishery research useful will be qualible by 1075.

A new highly sophisticated 112 feet fishery research vessel will be available by 1975. The University has a computer centre featuring a 64-K Nox computer, there is a DCT 2000 Simulator connected to a UNIVAC 1110 at the University of Bergen, and DCT 1000 Simulator is under construction.

Tromsø lies north of the Arctic Circle (lat. 69°), but has a mild climate because of its coastal position. There are two months of midnight sun and two of darkness. There are fine opportunities for outdoor life.

Salaries: Professor 104.780, Lecturer 69.760 to 87.510 N. Kr. per year. The University will help with housing and other problems. Applications should be sent by December 12, 1974, including five copies of curriculum vitae and three sets of relevant publications.

Formal applications should be addressed to: Universitetet i Tromsø, Postboks 635, 9001 Tromsø, Norway. Further enquiries should be addressed to Professor A. H. Weatherley, same address. (1941)

#### CENTRE FOR OVERSEAS PEST RESEARCH Porton Down, Salisbury, Wilts

ASSISTANT SCIENTIFIC OFFICER

Routine maintenance of colonies of several insect pests of agricultural, veterinary and public health importance: moths, flies and mosquitoes. Bioassay of insecticides, viruses and other pest materials.

control materials.

Qualifications: Four "O" levels including English and a science subject.

Salary: £887 to £1,899, according to age.

Application forms from Miss M. B. McKiernan, Centre for Overseas Pest Research, College House, Wrights Lane, London W8 SSJ. Ref. COPR/3/4/64. Closing date: November 30, 1974.

#### UNIVERSITY OF RHODESIA DEPARTMENT OF AGRICULTURE LECTURESHIP/SENIOR LECTURESHIP IN CROP SCIENCE

Applications are invited from suitably qualified graduates for a post of Lecturer or Senior Lecturer in the field of Crop Science, which includes specialised treatment of crop physiology, pasture science and the production of field, forage and horticultural crops. The successful candidate will have, in addition to a basic knowledge of the botany of agriculturally important crops, research experience in one of these special areas.

Salary Scales (Approx. Stg. equiv.): Senior Lecturer: £5,597 by 124 to £7,389; Lecturer Grade 1: £5,087 by 188 to £5,839; Lecturer Grade 11: £3,135 by 161 to £3,618 by 179 to £3,976 by 188 to £4,728 by 179 to £4,907.

Family passages and allowance for transport of

Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid schemes.

aid schemes.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications, and naming three referees, should be submitted by December 15, 1974, to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP.167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained, Applicants from outside Southern Africa should send a copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. (1927)

#### THE UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF BIOLOGICAL SCIENCES

#### VISITING LECTURER

Applications are invited for a Visiting Lecturer in the Department of Biological Sciences, for one year, to assist in the teaching of environmental studies and to contribute to some aspect of the research in the department.

Salary will be within the range £2,118 to £2,580 per annum.

Requests for further details and application forms (which should be returned within 14 days of the appearance of this advertisement), should be sent, quoting Ref. No. 003/6 to Staff Officer, the University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. (1928)

#### FELLOWSHIPS AND **STUDENTSHIPS**

### UNIVERSITY OF CALGARY

#### DEPARTMENT OF **PHYSICS**

Applications are invited from suitably qualified persons (M.Sc. or Ph.D.) for a position as Research Assistant/Postdoctoral Fellow in the field of experimental/observational AERONOMY. Interest and/or experience in near infrared atmospheric emissions considered advantageous.

Write for further information and giving resume of background to: Professor A. W. Harrison, Department of Physics, Calgary, Alberta, Canada, T2N 1N4. (1774)

### NATIONAL RESEARCH DEVELOPMENT COUNCIL

Applications are invited for two N.R.D.C. Fellowships. The successful candidates will work under the direction of Dr K. Jewers at the Tropical Products Institute on the isolation and transformation of biologically active compounds from tropical plants. The Fellowships are tenable for one year in the first instance with the possibility of renewal subject to satisfactory progress being made.

Applicants should have a degree or equivalent in chemistry plus at least two years' postgraduate experience.

Salary in the region of £2,689 per annum plus an annual leave allowance of 22 days.

### NRDC Research Assistantship

Applications are also invited for an N.R.D.C. Research Assistantship. The successful candidate will work under Dr K. Jewers at the Tropical Products Institute of the pharmacology of biologically active constituents isolated from tropical plants. This post is also tenable for one year in the first instance with the possibility of renewal for a further period subject to satisfactory progress being made.

Applicants should have a degree or equivalent in pharmacology. Salary £1,820 to £2,040.

Application forms for both these posts from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London ECTR 5EB.

(1892)

#### UNIVERSITY OF BRISTOL

### JOINT RESEARCH PROJECT

for a period of three years, has been arranged between Plant Protection Limited, I.C.I. Jealott's Hill Research Station, and the Department of Physical Chemistry, University of Bristol, under the joint I.C.I. Fellowship scheme for work on the fundamental parameters which control the properties of concentrated colloidal dispersions.

Applications are invited for the post of post-doctoral fellow to carry out research on this project. The salary will be in the range £2,247 to £3,108 per annum, F.S.S.U.

Applications should be sent to Professor R. H. Ottewill, School of Chemistry, University of Bristol, Bristol BS8 1TS. (1856)

### UNIVERSITY OF STRATHCLYDE

Applications are invited from graduates in Physics, Chemistry, Chemical Physics or other relevant disciplines for an S.R.C. POSTDOCTORAL FELLOWSHIP in the DEPARTMENT OF CHEMISTRY.

The successful applicant will work on Energy Transfer Studies using the tunable SPIN FLIP RAMAN LASER in collaboration with Drs. R. T. Bailey and F. R. Cruickshank.

The post is for one year in the first instance with possibility of extension for one further year. Salary up to £2,247 per annum plus threshold payments, placing according to age and experience.

Applications (quoting R40/74) to Dr. R. T. Bailey, Department of Pure and Applied Chemistry, University of Strathelyde, Thomas Graham Building, 295 Cathedral Street, Glasgow G1 1XL. (1893)

#### UNIVERSITY OF NEW ENGLAND Armidale, New South Wales

#### RESEARCH FELLOW-AGRONOMY AND SOIL SCIENCE

A vacancy exists for a postdoctoral research fellow in the Department of Agronomy and Soil Science to work with Dr Graeme Blair on aspects of phosphorus turnover rates in pastures. Of particular interest is a study of factors regulating the pool size and turnover rate of organic phosphorus.

The appointee will be expected to develop his/ her own programme of research within the framework of ongoing field studies of phosphorus cycling in pastures grazed by sheep and cattle. This is a joint programme under study at Grafton and Tamworth in northern New South Wales and funded by the Australian Meat Research Committee

The Department of Agronomy and Soil Science has field, glasshouse and controlled environment facilities available as well as automated equipment for analytical and radioassay work.

The appointment will be for one year initially with possible extension to three years dependent upon satisfactory performance and availability of

Salary \$A9,002 to \$12,352.

Further information can be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.
Applications close on November 30, 1974.

### THE POLYTECHNIC CENTRAL LONDON

#### School of Engineering and Science Bio-Organic Research Group

Applications are invited for a Research Assistantship or a Research Fellowship (postdoctoral) for work on the entry of drugs into mammalian cells in culture. The successful candidate for the Research Assistantship will be expected to register for a higher degree.

Research Fellow £2,151 to £2,331 Research Assistant £1,544 to £1,654 Application form from: The Establishment Officer, PCL, 309 Regent Street, London W1R 8AL.

(AK1926)

#### FLINDERS UNIVERSITY OF SOUTH AUSTRALIA RESEARCH FELLOWSHIP IN BIOLOGY

RESEARCH FELLOWSHIP

IN BIOLOGY

Applications are invited from suitably qualified persons for a Research Fellowship tenable within any of the fields represented in the School of Biological Sciences of the University. The Research Fellowship is tenable initially for one year but application may be made for a further year. Applicants should have completed a Ph.D. degree prior to October 31, 1974, or have had equivalent research experience.

The appointment will be made according to qualifications and experience within the salary range \$A8,184 (3 by \$342) (1 by \$313) to \$A9,523. A grant not exceeding \$A500 may be made as contribution towards the travel costs of the Fellow in taking up the Fellowship.

The School of Biological Sciences is an integrated school, without sub-divisions into separate departments. Research conducted in the School includes the following fields of study: Behavioural Biology (drug tolerance, neurotransmitters and learning), Biochemistry (regulation of growth, carcinogenesis by polycyclic hydrocarbons, purine analogues, control of D.N.A. synthesis, chromatin sub-structure, cytokinins, effects of aldosterone and analgesics on kidney), Biophysics (energy conservation in photosynthesis, fast movements in plants, solute transport by plant glands, vision physiology and anatomy), Cytotaxonomy (of arid zone flora), Developmental Biology (germ plasma in Anura, reproductive embryology, nuclear transplantation). Genetics (population genetics, radiation and chemical mutagenesis, genetics of Drosophila compound chromosomes. Drosophila development), Immunology (mechanisms of self-tolerance, adjuvants, murine leukaemia viruses). Microbiology (control of viral macromolecular synthesis, viral pathogenesis, genetic control of recombination in Neurospora), Physiology (Animal) (locomotion, temperature and water homeostasis, responses of liver and abdominal nerve receptors to various stimuli, physiology and paleobiology of marsupials). Physiology (Plant) (structural and functional relationships between the plan

species).
Further details concerning the staff of the School and their fields of interest are obtainable from the Registrar, The Flinders University of South Australia. Budford Park, South Australia 5042.

Applications, including full personal details, details of academic record and publications, a brief outline of research interests and names of at least two referees, should be lodged with the Registrar by December 1, 1974. Each applicant should ask his or her referees to forward their reports directly to the Registrar before the closing date. (1865)

#### ALCOHOLISM M.C.A. RESEARCH FELLOWSHIP

The Council offers a Fellowship of 2 or 3 years to a medically or scientifically qualified worker for research into the cause, detection or prevention of alcohol dependence. The financial support will be adjusted to the experience of the worker and the demands of the proposed research. Full information from: The Executive Director, The Medical Council on Alcoholism, 8 Bourdon Street, London WIX 9HY. (1864)

#### TWO POST-DOCTORAL FELLOWSHIPS IN THE EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following Fellowships.

Two Post-Doctoral Fellowships, each awarded for a period of one year (extendable to two years in special instances) beginning in September, 1975, with a stipend of \$12,000 per annum. Completed applications are to be returned by February 15. Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York, 10964

Award announcements will be made March 31, 1975.

#### UNIVERSITY OF OTAGO Dunedin, New Zealand TEACHING FELLOW IN THE FACULTY OF SCIENCE

Applications are invited for a Teaching Fellowship available in Departments of the Faculty of Science. Duties will include teaching and research, the latter normally being directed towards the degree of Ph D degree of Ph.D.

Stipend: NZ\$3,913 per annum for two years. NZ\$4,160 for the third year.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH 0PF or from the Registrar of the University.

Applications close on November 30, 1974.

#### UNIVERSITY OF MELBOURNE RESEARCH FELLOWSHIPS

Several fellowships are awarded twice each year for full-time research in any department of the University.

Eligibility: Ph.D. or at least equivalent research experience

Tenure: 1-2 years.

Salary:

\$9,002 (Australian), (currently equivalent to U.S. \$13,368 or £5,761), \$485 annual increment, plus return air fare.

GRANTS-IN-AID AND TRAVEL GRANTS Several grants-in-aid are also awarded twice each year to academics on salaried leave to conduct full-time research at the University.

Detailed information from the Secretary for Graduate Studies, University of Melbourne, Parkville, Victoria, 3052, Australia or from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close January 31, 1975. (1870)

#### UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS

#### SENIOR RESEARCH FELLOW or RESEARCH FELLOW

Applications are invited for a Postdoctoral Fellow for research on the spray from motor vehicles. The research is part of a continuing programme strongly biased towards experiment and is aimed at improving the understanding of the basic mechanisms and pointing to practical solutions of the spray problem. Salary will be dependent on qualifications and experience and is within the range £2,100 to £4,000 per annum plus threshold payments and F.S.S.U. benefits.

Applications, including curriculum vitae and the names of two referees, should be sent to the Deputy Secretary's Section (Ext. 2400), The University, Southampton, SO9 5NH, quoting reference 323/R/NA. Closing date November 30, 1974.

#### GIRTON COLLEGE CAMBRIDGE

Applications are invited for a SCIENTIFIC RE-SEARCH FELLOWSHIP open to women graduates and tenable for three years from October 1, 1975. The applications should be in the field of Mathe-matics, Natural Sciences, Geography and allied

Each Fellowship is to the value of £1,000 per annum and pensionable. Particulars are available from the Secretary to the Council, Girton College, Cambridge, to whom applications should be sent by January 8, 1975.

#### UNIVERSITY OF STRATHCLYDE

Applications are invited from CELL BIOLOGISTS for a RESEARCH FELLOW-SHIP (Postdoctoral preferred) in the DEPARTMENT of PHARMACEUTICAL TECHNOLOGY starting as soon as possible, to work until December 31, 1976, on drug actions on cultured human cells.

actions on cultured human cells.

Salary range £2,118 to £2,412 plus threshold payments and F.S.S.U.

Applications (quoting R41/74) with curriculum vitae and names of two referees to Dr Mary Dawson, Department of Pharmaceutical Technology, University of Strathclyde, Royal College, 204 George Street, Glasgow G1 1XW, from whom further particulars may be obtained (Tel: 041 552 4400 Ext. 2113).

#### CRYOGENICS RESEARCH UNIVERSITY OF SOUTHAMPTON

#### POST-DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for the following two year appointment to commence as soon as possible.

#### L.N.G. HEAT TRANSFER

To measure 2 phase condensing heat transfer coefficients on large rig at A.E.R.E., Harwell for L.N.G. heat exchangers.

Applicants should have experience in mechanical/chemical engineering or low temperature physics.

Salary in range £2,250 to £2,600 (plus F.S.S.U.)

Applications with names of two referees to the Deputy Secretary's Section, The University, Southampton SO9 5NH. Please quote reference 254/R/Na. (1912)

#### **GRANTS & SCHOLARSHIPS**

#### UNIVERSITY OF SYDNEY THE HENRY BERTIE AND FLORENCE MABEL GRITTON POSTGRADUATE RESEARCH SCHOLARSHIP

Applications are invited for the abovementioned Scholarship from graduates of any university within the Commonwealth, or from graduates of any university who are British subjects. The Scholarship, which is tenable in the University of Sydney, will be awarded in the first instance for one year, and may be renewed for a second year and, in exceptional cases, for a third year.

The scholar will be expected to undertake post-graduate research in Chemistry as it is related to Industry or Agriculture.

Depending on an applicant's qualifications, the Scholarship will be awarded in either the senior grade (in the range of \$A7,270 to \$A8,413 per annum) or the junior grade (stipend \$A3,550 per annum), plus other allowances where appropriate. At either grade, a travel allowance is provided.

Applications, which should include a certified copy of the applicant's academic record and the names of two referees, close with the Registrar, University of Sydney, N.S.W. 2006, Australia on January 17, 1975.

Further information and application forms may be obtained from the Registrar's office. (1871)

### £600 POST-GRADUATE **GRANTS**

### **MSc Dairy Science** at Reading University

The Dairy Industry offers a limited number of special grants worth £600, plus all fees, for the one-year MSc course in Dairy Science at Reading

This post-graduate course is available to holders of first degrees or equivalent qualifications in pure or applied science (including agriculture).

The awards are designed for those students who show outstanding potential for responsible scientific, technical and managerial positions in the processing and manufacturing sides of the Dairy Industry.

The MSc qualification could also lead to lectureships in dairy science and technology.

Applicants must be resident in the United Kingdom, and intent upon taking up employment in the United Kingdom Dairy Industry on completion of the course. All applications for the 1975 award must reach us by 31 January 1975.

For full details, please write to, or

R D Lemmer Esq., Department 11, The Dairy Industry Training & Education Committee, The Joint Committee, Giggs Hill Green, Thames Ditton, Surrey KT7 OEL. Tel:01-398 4101. Ext. 436.

WM. DAWSON & SONS LTD. Back Issues Department, Cannon House, Park Farm Road, Folkestone, Kent, England. Tel.: Folkestone 57421.

#### LECTURES AND COURSES

#### UNIVERSITY OF LONDON:

A course of three lectures entitled "The Population Biology of Plants" will be delivered by Professor J. L. Harper (Bangor), at University College (Chemistry Auditorium), Gower Street, W.C.1, on November 26, 27 and 28 at 5.30 p.m. ADMISSION FREE, WITHOUT TICKET Academic Registrar (1904)

# **EUROPEAN MOLECULAR BIOLOGY ORGANISATION**

Postgraduate Course

in

# Advanced Animal Virus Genetics and Molecular Virology

An E.M.B.O. study course in Advanced Animal Virus Genetics and Molecular Virology will be held in the Institute of Virology, University of Glasgow, from March 16 to April 4, 1975 under the direction of Professor J. H. Subak-Sharpe. The intensive laboratory periods will be supplemented by 15 lectures as well as specialised discussion. In addition there will be 7 special guest lectures.

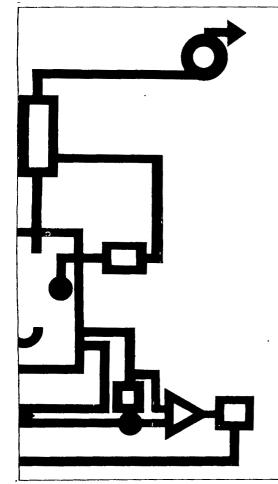

The Course will be particularly appropriate for research workers in the field with three or more years postgraduate research experience as the programme will cover more recently developed techniques used in the genetic and biochemical analysis of animal virus systems, for example, triparental cross recombinants, restriction enzyme fragment analysis, or application of enucleate cells in animal virology.

The fee is £90 excluding accommodation. The number of places is restricted to 16. Limited E.M.B.O. funds are available to help those applicants who could not otherwise attend.

For further details and application forms write to:

Professor J. H. Subak-Sharpe, The Course Director, The Institute of Virology, Church Street, Glasgow G11 5JR, Scotland. Closing date for applications is January 6, 1975. (1903)

### **Gas Analysis Instrumentation**

Anthony Verdin

The detection and analysis of gases and vapours has become essential in many areas of modern life; noticeably industrial safety and control of the environment. As a result a whole class of physio-chemical methods has come into existence. The author draws on his fourteen years of experience in the field to supply the only wide-ranging view of all types of equipment presently available. Both academics and industrialists will find it indispensable.

### **Electrical Breakdown in Gases**

Edited by J. A. Rees

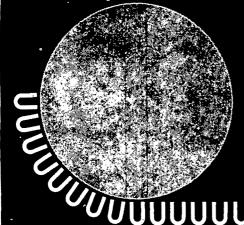

The electrical breakdown of gases has been studied in the laboratory since before the start of this century and it is sixty years since Sir J. S. Townsend wrote his monograph *The Theory and Ionisation of Gases by Collision.* In that time the subject has been widely studied and a great deal of progress has been made in understanding many aspects of the problem. J. A. Rees has selected the major papers in this field and has linked them with comments and an introduction. Reprinted from the the original sources, the papers together provide a unique introduction to the ionisation of gases.

# Introduction to Space Charge Electron Optics

G. A. Nagy and M. Szilagyi

This introduction to space charge electron optics is an updated translation of an original Hungarian publication which presents to the West for the first time a comprehensive survey of the vast work carried out in this field in the USSR and Eastern Europe. It is however more than just a summary of literature as it also contains the solution of many problems and so points the way to future developments.

#### PhSeX (X=Br, Cl or PhSe)

The observation that alkyl phenylselenoxides undergo eliminations at room temperature to form olefins 1-3 is the basis for a new and convenient synthesis of allylic alcohols, 4 allylic ethers and acetates,5 and α,β-unsaturated carbonyl compounds.6-8 Diphenyl diselenide is a yellow, odorless, air-stable solid which is easily converted into the highly colored phenylselenenyl halides. The oxidations are conveniently carried out at or below room temperature, using a variety of oxidants (peracetic acid, sodium periodate, hydrogen peroxide, etc.).

"A slow sort of country!" said the Queen "Now, here, you see, it takes all the runnin you can do, to keep in the same place. If yo want to get somewhere else, you must run a least twice as fast as that!"

# **YOUR FUTURE ELECTRON** OPTICS...

### WILLYOU WANT. A SYSTEM THAT **CAN GROW ALONG WITH** YOUR NEEDS AND YOUR BUDGET?

As electron microscopes approach the theoretical limits to resolution, their useful lifetime is extending dramatically

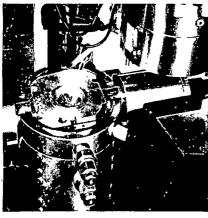

The problem... if you want to call it that... is that other aspects of electron optics are still being improved. New ways of getting more information from a point in a specimen are continuously being developed How can you benefit from this growing technology... without buying more than you need, or replacing your instrument every few years?

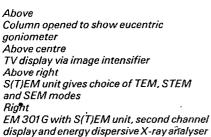

Philips' answer is the systems approach to electron optics. No matter what your future holds... there's a Philips microscope for you now!

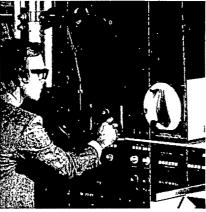

For example. Start with the advanced research EM 301 (or your EM 300). Add a goniometer for tilting capability. Add a S(T)EM unit later, and you'll have, at your fingertips, instant choise of TEM, STEM or SEM. Add an energy dispersive x-ray analyser for micro-chemical analysis. Choose from a full range of cameras, TV displays, image intensifiers and video recorders. Add on when your ready... without ever compromising the excellent versatility of the basic instrument.

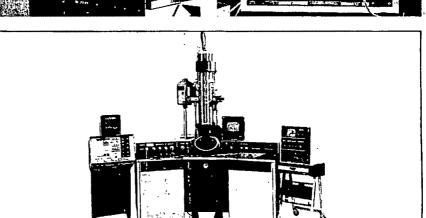

Highest performence... plus inherent versatility extending far into the future. It's yours with Philips. Order a Data File and see.

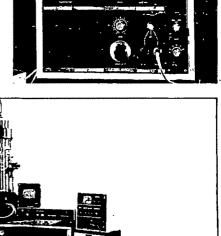

Philips Industries Electron Optics Department Eindhoven - The Netherlands

#### Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e<sup>a</sup> if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. See any contemporary Nature for style, but note:

- (i) To refer to several references by the same author at once, only one reference number need be given.
  - (ii) Cite first and last pages.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-bepublished volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width.

The originals should be about as wide as a page of Nature. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. We are always glad to see artwork for possible use on the cover, whether or not it is associated with a manuscript, but cannot guarantee the return of material.

A fuller guide appeared in Nature (246, 238; 1973).

Phytoalexin production by live cells in broad bean leaves infected with Botrytis cinerea—J. W. Mansfield, J. A. Hargreaves and F. C. Boyle  Data processing by the chemotaxis machinery of Escherichia coli— J. S. Parkinson

# Academics in the boardroom

A FEW years ago a colleague working in a university was approached by an establishment of the Ministry of Defence with an invitation to become a consultant on some matters in which he was an expert. He underwent an extensive security grilling (the establishment had an unenviable record of leaks and was sensitive to recent criticism) and a year later was pronounced fit to be consulted. After the first few days at the site he returned to his university where several weeks later he was called by the head of the section for which he had consulted. "I'm terribly sorry to trouble you", he said, "but can you tell me whether you think your daily rate for consulting should be £4, £7 or £10?"

Is consultancy worth anything at all beyond those few pounds sterling either to industry or to universities at present? The question is touched lightly upon in The Universities and Applied Research, the proceedings of a day's symposium of industrialists and university scientists earlier this year, published by the Research and Development Society (47 Belgrave Square, London SW1; £4.50). The meeting was organised to look at the relevance of applied research in universities to social and industrial needs. One of the subjects which obviously came in for some attention was the ability of university staff to be responsive to industry—assuming they wished to—and there seemed to have been general agreement that consultancy was a good thing. Thus Professor G. V. R. Born (University of Cambridge) saw consultancy as "a fascinating assignment ... a less expensive way of providing industry with information and ideas [than taking similar persons on full-time]". And Professor K. Hoselitz (Mullard)—"university consutlants (were) a useful way of forming a bridge". And Dr A. Spinks (ICI) "strongly approved of consultants". Can one therefore be satisfied that the consultancy system is an adequate means of broadening the understandings between industry and university, or is there more that could be done in the creation of formal machinery for the movement of highly intelligent people?

Despite the good intentions expressed above, there are many who regard consultancy cynically. On the university side there are those who give very poor value for money, who refuse to see industry in any broader perspective than that of the immediate problem presented to them or who dump the work on their students as unpaid sub-consultants. There are those who arrange with colleagues to provide mutually contradictory advice so that they can profit by regular recapitulation of the same opinion to a confused managing director.

On the industrial side there are many who employ consultants simply because it is a prestigious thing to do. Others do not use consultants for ideas or criticism but to provide an academic rubber stamp for their activities and a reassurance that they are not making asses of themselves.

Obviously the value of a consultancy depends entirely on the calibre of the two parties to it in each case, but there seems to be a need in many instances to go beyond the rather flimsy structure that the arrangement has at present. One of the biggest difficulties of an ad hoc scheme is that the consultant is insufficiently tied to the organisation for which he consults. He is not brought far enough into the corporate decision making nor the day-to-day running to feel deeply identified with the need for the company to be profitable. He is also likely to be fed problems which the company believes he might be able to solve—and which the company may have gone to some trouble to concoct for him—rather than be invited to roam around and pick up the problem that seems to him most important.

Many of those in applied research and a few of those in pure research in universities have had some industrial experience, but the number has been declining in recent years. Much of this experience, however, is at the junior scientific and technical level. What is now needed is more opportunities for the process of consultancy to move towards one in which it would be natural for senior university staff to consider a spell of up to several years in industry at the boardroom level. There is no doubt that many academics would find the industrial challenge stimulating and many industries would welcome new blood at the executive level. In addition the still rather distant relationships between industry and university in Britain could not but be helped by this.

The biggest problems are those man-made difficulties of tenure and pensions. It is ridiculous the extent to which careers become controlled by these constraints. There is hope that the quality of some pension schemes and their interchangeability will improve in the next year or two. The problem of university appointments remains and is not easily solved. It needs some imaginative thinking.

### A hundred years ago

THE Journal of the Society of Arts states that M. Mège Mouriès, after analysing butter, has succeeded in making it synthetically. This imitation butter, recognised by the Conseil d'Hygiène as indistinguishable from real butter, is finding its way into the Paris markets at half the present price of real butter.

From Nature, 11, 76, November 26, 1874.

# For those in peril: 2

Charlie Clutterbuck, Alan Dalton and Andy Solandt, of the British Society for Social Responsibility in Science, consider what action needs to be taken to identify and regulate industrial health hazards.

Over the past two decades the petrochemical industry has expanded more rapidly than any other. It is estimated that thousands of new chemicals are introduced into the production processes of the industry each year. One such chemical is vinylchloride monomer (VCM), which is used in the production of one of the world's most important plastics-PVC (polyvinylchloride). Unlike most of the new chemicals introduced into the work environment. VCM has been fairly well studied and was thought to be non-toxic. From being a harmless' compound twelve months ago, VCM is now, however, being described as "the occupational hazard of the century" (William Lloyd, United States National Institute for Occupational Health and Safety.) What then might be the dangers of those countless other chemicals that have never been tested as health hazards?

Dr Epstein of Case Western Reserve University Medical School, a specialist on industrial carcinogens, asserts that "In the absence of pre-testing, the the worker himself or herself, is unwittingly used as an involuntary test subject, to whom data are not generally available, if indeed they are ever collected and analysed." (Regulatory Aspects of Occupational Carcinogens presented to an International Chemical Federation Conference in Geneva in October 1974.) As a result of this post hoc procedure the health and livelihood of people on the shop floor and in the monitoring labs of industry are in constant jeopardy.

What can the concerned scientist do to help improve this disgraceful situation? One possible answer was suggested by Peter J. Smith in Nature (October 18). He proposed that scientists should admit moral responsibility for taking a clear lead in seeing that the ill effects of science and technology are eliminated or at least mitigated." He then went on to suggest that the ways in which scientists could take this 'clear lead' was to do thorough research on health hazards and to ensure that the results of this research be made public. He realised that this work had to be supported by vigorous campaigning to acquire the necessary finances. He also recognised some of the difficulties in .

obtaining statistics on health hazards. "Of course, employers frequently attempt to justify their refusal to disclose vital information on the grounds of commercial secrecy—a ploy which is sometimes legitimate, sometimes not."

Unfortunately, however, he was not at all clear on where this information should go and on how it could be presented in order to achieve maximum impact. Clearly the usual procedure of merely publishing in academic journals would accomplish little. Perhaps, as Smith implies in his article, the information should go to a body of elite scientists which would have "an immense potential for influencing public and government opinion." And is it merely opinion that we want to change?

The British Society for Social Responsibility in Science (BSSRS) has been actively combatting some of the hazards of work over the past year. Although this by no means makes us 'experts' in occupational health, it has furnished us with enough experience to enable us to offer a fairly concrete and systematic alternative to Smith's proposals. Before we describe this alternative we describe a case history which is a typical example of the handling of health hazards in industry.

In 1961, a medical officer at a Dow Chemical plant in the United States, discovered that VCM was the probable cause of serious liver damage in a number of men in the plant. On the basis of this, Dow drastically reduced its TLV (threshold limit value or maximum 'safe' time-weighted average) for VCM to 50 p.p.m. This action was made public. But none of the other PVC manufacturers followed Dow's lead. We had to wait until one man, Earl Parkes, had taken B. F. Goodrich of Kentucky to court twice to obtain compensation for his liver damage before the knowledge of the dangers of VCM became widely publicised. (Earl Parkes and two other men at B. F. Goodrich subsequently died of the liver cancer angiosarcoma.) So far, one death due to angiosarcoma has been confirmed in Britain. Recently VCM has been associated with lung cancer, painful swelling of the joints of the hands and feet and degeneration of the central nervous system.

Now that the dangers of VCM are widely known, what is being done to protect people from exposure to it? In both the United Kingdom and the United States, industry has adopted emergency standards of 50 p.p.m., with a time-weighted average of 25 p.p.m. The Department of Employment has

set up a special committee to determine a code of practice for VCM; it is important that it reports soon. It has been deliberating for 6 months already and apparently it has not as yet even discussed the problem of a TLV.

Perhaps it will adopt the recent OSHA (Occupational Safety and Health Act in the United States) standard of 1 p.p.m. While this reduction is a welcome improvement however, it must be recognised that the TLV is only a small part of the problem. For even though a relatively low standard has now been set for VCM the OSHA has completely ignored a special committee's report on ways of enforcing this standard. Dr Epstein has made this comment on OSHA's recommendation: "However, the major key provisions of the Committee, including those endorsed by corporate scientists on the Committee, were disregarded by OSHA, presumably under strong industrial pressure." These included recommendations of the committee to ensure the effective implementation of the carcinogen standards by instituting sensitive environmental monitoring systems and a permit system. (Regulatory Aspects of Occupational Carcinogens presented to the ICF Conference, Geneva, 1974.) We can only hope that the new United Kingdom Commission on Health and Safety at Work will prove to be more stringent and independent in its approach to the problem.

It is too early for BSSRS to define clearly 'workers' science'. Even so, there are a number of general guidelines which we can propose at this time based on our own work on VCM hazards at a BP plant in Fort Talbot. These guidelines apply to any 'expert', whether technical, medical or scientific, working in the occupational health field. They also apply to those technical people working in industry who feel that there is a clear and immediate need for action on occupational health in their own industries.

• Try to work primarily with the men and women who are actually exposed to the health hazard. This does not mean that one should ignore other groups interested in occupational health. Clearly, both scientific and shop floor workers must seek the help and cooperation of management and government bodies interested in these problems. Management should be consulted and valuable information exchanged. The Factory Inspectorate and/or the Public Health Office should be approached. With the new powers invested in it by the Health and Safety at Work Act, the Factory Inspectorate

•

١

may prove to be a valuable partner for any groups seriously working to reduce health hazards in industry.

Liaison with the Trades Union involved is of paramount importance. For it is they who have experience of negotiating with management and they who have at their disposal, the services of the independent Centenary Institute of Occupational Health which specialises in the chemical analysis and medical evaluation of questionable materials.

• Remember that your main reason for being on the 'shop' floor is to exchange information and experience. The people on the shop floor can give you first hand knowledge of the processes they work with and the hazards that these processes involve. They can tell you how their plant/office actually works, not just how it is supposed to work. For your part you can help these men and women to understand the technical/medical explanation of the hazard and how to monitor and keep

the necessary records of the hazard.

- Unfortunately, even the introduction of reasonable health conditions is an issue which often involves conflicts with employers. Recently 5,000 men and women at the Shell/Chevron plant in California had to strike for 5 months just to have seven medical provisions written into their contract. This was done in the light of the fact that all the other major petrochemical companies in the United States had already agreed to medical provisions being written into their contracts. The scientist must be prepared to stand up in defence of working people. This may mean pressing their case in joint management/union committees or even standing up in court to put the facts as they see them. Two men in the United States, Dr Selikoff of Mount Sinai Hospital in New York and Dr Epstein, have actually done this.
- Be prepared to use the press and television to publicise your case. The BSSRS helped World in Action to do

the first exposé of the VCM problem in this country. Later we devoted 15 minutes of an Open Door programme (BBC2) to a discussion of the VCM issue.

• In cooperation with other scientific, production line, and office workers, press for the implementation by the government, management and trade unions of systematic pre-testing of industrial processes and materials for possible health hazards.

Clearly it is not enough for individual scientists to become involved in isolated local health hazard issues. There must be a coordinated body for scientists participating in the field of occupational health. This is precisely the role that the BSSRS has begun to play and hopes to develop systematically and comprehensively in the future. We cannot afford to finance teams of investigation or the much needed thorough long term research in this area. We hope, however, to be able to serve as a vital catalysing agent.

# international news

MINISTERS from 24 countries, including Britain's Denis Howell, met in Paris last week at the first meeting of Environment Ministers convened by the Organisation for Economic Cooperation and Development (OECD). The ministers met to discuss several recommendations put forward by the environment group of the OECD on the formulation of rational and coherent environment policies throughout the OECD countries.

One of the concepts discussed at the recent meeting was in fact accepted in outline in 1972, namely the Polluter Pays Principle', which in effect means limiting state aid for pollution control to industry while making it conform to certain standards. This will then mean that goods made by polluting industry will be more expensive, as they have to pay for their own pollution control. The consumer, it is argued, will therefore prefer the cheaper goods made by non-polluting industry. Some countries have already incorporated the principle in their legislation, although, exceptionally, state aid may be allowed.

The ministers also discussed the OECD's proposed code of conduct for dealing with the problem of transfrontier pollution. One of the main points of the code is that pollution exported to other countries must not exceed the levels permitted within the polluting country.

The most widely discussed instance

# OECD urges environment policies

by Eleanor Lawrence

of this type of pollution, as far as Britain is concerned, is the sulphur dioxide from Britain and from continental Europe which ends up over Scandinavia as acid rain, with dire environmental consequences. The OECD is at present in the middle of an international survey of air pollutionthe first such survey to use completely standardised monitoring methodswhich should clarify this situation. Commenting after the meeting, Mr Howell said that Britain might have to reconsider her power-generating policy if the results of the survey showed that sulphur dioxide emissions from power stations were the 'culprit'.

The problem of trans-frontier pollution also raises the question of whether people affected have the same rights in the polluting countries' courts as would citizens of those countries in the same situation. But unfortunately, even the citizens of some countries find it extremely difficult to gain standing on matters of pollution in the courts, so that this might prove to be an empty privilege.

Complications and inequalities could also arise because of the fundamental difference between the judicial structures in the various countries—Europe by and large follows Roman law whereas in Britain there is the added complication of being able to bring prosecutions under common law, which operates on a precedent system rather than on the basis of published statutes.

There is also the problem of who exactly is liable to prosecution. If treaties for lower pollution had actually been signed between polluted and polluting countries, the defendant might well be the Government in the person of the Secretary of State for the Environment. Other problems would, of course, be the usual ones which bedevil pollution legislation generally, such as collecting sufficient data to make a case which will be accepted in the courts in the first place.

At present, if an article manufactured in Britain is sent abroad and proves to be harmful, it may well be the distributors in that country who are prosecuted and not the manufacturing company. This has happened in Australia in the case of thalidomide, marketed there by a subsidiary of Distillers Company Ltd.

The effects of pollution will be far less easy to define in practice than even the effects of a manufactured article, and there is the prospect of a real field day for the lawyers.

"Nothing has happened to climate in the past few years that is not the sort of thing that has happened already in the past few centuries". These words from Dr J. S. Sawyer (pictured right) of the UK Meteorological Office, sum up the 'establishment' view of the present concern about climatic doom (see the review on page 335). Serious droughts and floods are part of the climatic pattern, and there seems to be nothing unusual about the present fluctuations. A crash programme of research, says Sawyer, is not the answer to the problems posed by such floods and droughts; there is a need for more people to be active in climatic research, but there is also a need for time for them to grasp the problem as a whole.

value of frequent claims that man's activities are affecting the atmosphere. nowhere near enough people to follow ceremonies and woe betide those who surface of the sea. up all the suggestions with detailed cannot deliver at the right time. ther extrapolation is fruitless.

On March 8, 1974, Mr U. Geller, who needs no introduction, demonstrated his metal-bending powers on Channel 79, Toronto. The two keys he selected from a large collection were the key to the Genetics Department and a Fellow's key to Trinity, number 13 "registered as issued to me personally". The genetics key was indubitably bent through 15°, though by what process we decline to speculate. Trinity's key remained unbent. Neutral observers will marvel not at Mr Geller's powers but at Dr Owen's ability to evade the Cambridge key audit for so many years.

### Arms and the common man

from Wendy Barnaby

A RECENT meeting in Lucerne left a distinct impression that if everything were left to expents-no matter how well intentioned—laboratories would be thriving while the lot of the common man would steadily deteriorate. The meeting, one of a series of conferences being held to update the 1949 Geneva Conventions, was called by the International Committee of the Red Cross to consider the prohibition or restriction of conventional weapons "that may cause unnecessary suffering or have indiscriminate effects". It was hoped that the discussions would pave the way for recommendations to the politicians, whose next conference will be from February to April 1975. Progress was, however, very slow.

Take the case of napalm. The meeting spent some time discussing whether it is an 'all-or-nothing' weapon: that is, whether a person escapes it altogether or is killed by no matter how small an amount he encounters. Statistics of deaths of American soldiers in Vietnam after napalm had accidentally been

dropped on them were quoted to prove that it is not such a weapon. Only four out of 53 men died. But the effectiveness of napalm against personnel varies greatly with the training, experience and equipment of the victims, and with the standard of medical treatment and the rapidity with which it is given. It is therefore spurious to use this figure as a basis for calculating the effects of drops on civilians. Soldiers are trained, equipped and often experienced-and these particular ones received all possible modern medical care 10-20 minutes after the accident. Small comfort for the peasants.

This all-or-nothing sort of argument only confuses the issue by inviting conflicting evidence and adding to the general confusion of the debate. After all, everyone agreed that severe burn wounds are probably the worst possible type of wound. Surely that recognition is more important than a precise determination of how much of the worst possible type of wound is necessary to kill. If military action is aimed at incapacitating the enemy, it is obviously inhumane to achieve this through severe burning when other, less traumatic means are available.

Many argued that the accuracy with which napalm can be delivered makes

its use more discriminate and therefore more humane than less accurate, high explosive and fragmentation weapons. A typical 100-gallon container scatters napalm over a reasonably clearly defined area of about one-quarter of a hectare, whereas artillery of typical accuracy has a circular error probable (the radius of the circle whose centre is the target within which half of the projectiles aimed at the target fall) of 10-20 metres and a range error probable of 30-60 metres. On this basis, napalm was said to have great military value in close air support operations, where it is desired to destroy specific targets near friendly troops. This argument would be all very well if we could be certain that napalm would only be used against structural targets and never against people. Unfortunately such certainty is impossible in any war. The military attractiveness of its accuracy cannot compensate for the risks taken with human suffering.

Similarly, the fact that the experts disagreed on the seriousness of wounds caused by high velocity bullets should not be allowed to paralyse efforts to restrict their use. The problem is urgent because European small-arms manufacturers have developed 5.56 mm guns capable of firing such bullets, which

they are hoping to sell to NATO countries to replace NATO's present 7.62 mm weapons. (In fact it was rumoured at the meeting that Denmark was waiting to hear the outcome of the discussions there before deciding whether to buy just such a new rifle). But again, the evidence was conflicting.

Dr B. Rybeck, the most senior medical officer in the Swedish navy, has carried out experiments on anaesthetised pigs in which he found that high velocity bullets could in general be distinguished from low velocity ones on inspection of the wounds caused by each. In other experiments in Sweden, anaesthetised dogs were shot with metal spheres in order to dissociate the usual tumbling effect of high velocity bullets from their other wounding effects. Blood from a dog which had been shot with a sphere was transfused into a second dog. When the impact velocity of the sphere was 1,000 metres per second the recipient dog suffered severe changes of regional blood flow after the transfusion—an effect not observed when the impact velocity of the sphere was 500 metres per second. Lieutenant Colonel Dr Robert Scott, of the Royal Army Medical Corps, has shot small calibre, high velocity bullets into blocks of gelatin and reported that these did in general produce a greater effect than 7.62 mm bullets, but only at short ranges. If the flight of the bullet into the gelatin was unimpeded, those of high velocity and low calibre deposited more of their kinetic energy in the gelatin than those of larger calibre and lower velocity; however, this was reversed if the bullets passed through a thin steel plate (to simulate the body of a truck, for example, under battle conditions) before entering the gelatin.

The politics of prohibiting the use of a shiny new gun, just when various countries are considering adding it to their armouries, are formidable. And yet there are hopeful signs. In the discussion on napalm, for example, the experts explicitly recognised that the politicians will have to take public opinion into account in determining whether it will be banned. It was even argued that the pressure of public conscience provided grounds for making the use of napalm illegal. So the common man does have a part to play. And he may well argue that he is more interested in establishing the principle of restriction of the use of various weapons, even if some doubtful cases do escape the net, than in allowing the discussions to bog down in technicalities while more countries acquire more harmful arms. In the case of the rifles, even the experts agreed that, in general, wounds caused by low velocity weapons such as pistols, carbines or

submachine guns are much less severe than those caused by rifles. If, on the basis of understandings as common as this, the public were to put enough pressure on the politicians, the experts could be forced to come up with some sort of restricting arrangement. But if the experts are left to devise categorisations of inhumane weapons to present to the politicians as a basis for action, the issues will simply be referred to more laboratories for more experiments the results of which will cause more disagreement. And in the meantime, as inhumane weapons spread to more countries, the danger to the common man will only increase.

# Van Wyk de Vries commission

from Graham Baker, Johannesburg.

South African universities for the most part enjoy considerable freedom of action in conducting their affairs, subject to the restriction of the country's race laws and in spite of some profound differences of opinion over political legislation between the government and the English-medium institutions in particular. The present undergraduate population of over 80,000 is growing at almost 10% a year and the universities are well aware of their obligation to make up for South Africa's acute shortage of skilled manpower, especially in the sciences and engineering. Furthermore, the government has of late become especially sensitive to the possibility that some universities might have become bases for political activity of which it disapproves.

It is therefore understandable that the academic community in South Africa has been eargerly awaiting the findings of a government-appointed commission of enquiry into white universities, which was tabled in Parliament on October 30. Under the chairmanship of Mr Justice J. van Wyk de Vries, the commission was set up in 1968, principally to consider the financing of universities but also to take a look at "student relations". The recommendations with regard to financing have been openly welcomed as giving the necessary boost for needed expansion. Thus, the commission proposes that up to 85% of running costs should be subsidised by the state and that existing and future capital debts should also be borne by government grants. In return, universities should pay an annual levy of R50 per student to the government. It has been noted that particular advantages from this will accrue to the smaller, more recently established institutions, which tend to be Afrikaans-medium campuses. It also means that universities

can only develop to an extent permitted by the amount of financial assistance provided by the state. Even so, these recommendations, if accepted by the government, are unlikely to come into effect before 1976 at the earliest.

The main sobjections to the report have been voiced in respect of its views on the non-financial aspects of university life, in particular the extent to which universities may be permitted to engage in political activity. The majority view of the commission is that if a university is politically active in a way the government sees as being 'irregular' and therefore outside its proper function, it will forfeit financial support from the state. Some vice-chancellors see in this a threat that universities must toe the ideological line of the government in power or suffer crippling consequences. They take this as interference with autonomy of the universities and, more bluntly, they see it as an attack on the English-medium universities in South Africa. The Afrikanns-medium institutions, in contrast, see an alignment with government policy as part of their social and political obligation.

Professor G. R. Bozzoli, Principal of the University of the Witwatersrand and a member of the commission, has spoken out strongly against this aspect of the report, as well as another, the 'finding' that South African universities were founded on a social order based on the principal of multinational separate development. As Professor Bozzoli points out, apartheid was only forced on the universities as a result of the Universities Act of 1959.

In a similar light, the commission rejects the view that universities should be free to make appointments without regard to race, colour or creed, and sees no merit in student bodies having representation on university councils and senates.

It happens that the Van Wyk de Vries Commission tabled its report only a few days before the Prime Minister, Mr Vorster, declared in a report-back meeting to his Nigel constituency that he needs just six months to bring about major changes in South Africa's social order, presumably a reference to legislation on race relations. The same message was also spelled out last week by some of Mr Vorster's colleagues at a congress of the Nationalist Party, doubtless a direct consequence of recent events at the United Nations and in neighbouring African states. Whether any moderation of government policy on apartheid will take the heat off the universities and permit any number of black students to be admitted once again to the white institutions, as some vice-chancellors would wish, remains to be seen.

#### Moon matters

SIR,—If your editorial "Bringing men to the Moon" (October 25) had been that of any journal other than *Nature*, we should have ignored it. In view of your prestige and of your great influence within the scientific community, we have decided to answer it.

You have sought to discredit this conference on a number of counts. You write, in reference to a previous conference, "while the scientists thought it silly, the philosophers took it all very seniously". In fact, at this meeting, only two of the 20 scholars were philosophers.

The purpose of the International Conference on the Unity of the Sciences is to further the field of communication between science and philosophy. The response of scientists to matters are naturally different from that of the philosophers. This indicates ignorance of modern philosophy.

Your sarcastic reference to the Second Conference in Tokyo is most surprising, since the conference itself was a success. Proceedings are available to those interested.

As to the 'messages of congratulation' by Nobel Laureates—messages of good-will, you must admit, can only be sent by the free will of those who send them. The manner of your reference to this indicates a prejudice. To write in this vein is nothing less than to despise a person, whoever he may be.

You attribute the most sinister possible motives to the founder of the organisation under whose auspices this conference is taking place. Surely Mr Moon, as any other philosopher of science living in the free world, is quite free to be devoted to any philosophy that he may choose for himself. Would it be unnatural to think that the initiator of the International Conference holds a specific point of view.

The aims, purposes and the nature of the Foundation, as admirable as they are, as set forth in the conference brochure, were clear and precise. Unfortunately, however, your statements about it seem to suggest that you had never read it.

You say that not all the advisers were very pleased to have their names used in this way. Basically, we have no intention of using the names of eminent scholars for purposes contrary to their own wishes. As you may know one person who agreed early on to

serve as an adviser subsequently chose to withdraw for his own reasons. As to our other advisers, both in the United Kingdom and internationally, they contributed greatly to the preparations of this significant event.

A feature of your editorial, unfortunately, is that general statements, even parts based on objective fact, demonstrate the prejudice and the apparent ill-intentions of the writer.

The list of participants you refer to was printed several months ago and included several names among which were firm acceptances as well as tentative ones. You have used this document to make allegations of improper conference management.

In reply to your enquiry: as founder of the Foundation under whose auspices this conference is taking place, Mr Moon has a right to be present and, contrary to your suggestion, he will, I understand, actually deliver the Founder's address.

It is suggested that in future you avail yourself of a more rigorous methodology for the purpose of discrediting those scientific enterprises of which you disapprove.

Morals are but an attempt to examine goals. And how can any behaviour be judged scientifically except in terms of its ability to achieve a goal? Any other criterion you must admit can only be purely subjective.

It may be true that there is, at present, no scientific methodology for the examination of basic goals, but the fault is surely with modern science for not having developed it. For until it is developed, scientists must accept their incapacity to examine the very assumptions on which their work is based. They must content themselves with doing things, without ever knowing why they should be done.

Contrary to what you intimate, we have no ideological bias. A number of scientists from the Communist countries were invited to this conference but, as it happened, could not attend.

It is suggested by way of conclusion that you ought to have taken the trouble to meet the person of central responsibility for the activity in question rather than questioning a subordinate employee whose knowledge may well be limited and even inaccurate.

In this case, I encourage you to accept the invitation extended to you in June this year, and to attend the Third International Conference on the

Unity of the Sciences, in order that you may evaluate its true value and import first hand, rather than relying on second-hand and perhaps unreliable sources.

In your allusion to 'their Boeing complex and their propensity to amateur philosophising', in reference to the eminent scientists, you have intentionally or unintentionally demonstrated your contempt and disrespect for those "deeply concerned scholars" who are willing to contribute to the urgent issues of the unity of science and the relation between science and morals.

P. BRIAN WIJERATNE ICUS, London SW1, UK

The 'subordinate employee whose knowledge may well be limited and even inaccurate' was the 'Chief Public Relations Officer.'—ED.

#### Chemicals and cancer

SIR,—Your October 11 issue summarised some of the issues in the Aldrin and Dieldrin Suspension Hearing.

I was attributed-incorrectly-with five criteria which must be met before there is sufficient evidence of human carcinogenicity. These criteria appeared in the Administrator's Opinion of October 1, and are not quoted from any statement made by me. An EPA attorney and an EPA witness caricatured my opinions by suggesting that I would only recommend the removal of a product from the market after cases of human cancer had occurred. This is not-and never has been-my opinion. To avoid any misunderstanding I submitted an additional statement on this topic to the hearing record on September 11, in which I also indicated that their belief was apparently based on my answer to the question whether we would take dieldrin off the market if human cancer cases occurred.

My affirmative answer did not imply that I would not give advice to that effect at an earlier stage. It is not my position that we must wait for human cancer before removing a product from the market.

I was, therefore, surprised to see in the Administrator's Opinion that my "demands are practically impossible to meet".

# Vaccination against malaria

ATTEMPTS to find a vaccine against malaria began in the 1930s but gave way to searches for new drugs during the war and anti-mosquito programmes after it. The combined use of anti-malaria drugs and insecticides has been one of the success stories of this century. The number of people infected with malaria has decreased considerably over the past decade in spite of the fact that, because of the increasing world population, more people than ever before now live in malarious areas. But resistance to drugs and insecticides, lack of money and political instability have reduced the future prospects of malaria eradication and thoughts have again turned to the possibility of developing a successful vaccine.

Three different sorts of vaccine are at present being investigated: irradiated sporozoites from the mosquito, extracts from schizonts (developing stages in the blood) and emulsified merozoites (the stages which pass between blood cells). After promising results using irradiated sporozoites in rodents, an experiment with Plasmodium falciparum in humans has resulted in one of three volunteers being protected against homologous (Clyde et al., Am. J. Med. Sci., 226, 169; 1973) and heterologous strains of the same parasite (Clyde et al., Am. J. Med. Sci., 266, 398; 1974). Earlier this year Simpson, Schenkel and Silverman (Nature, 247, 304; 1974) succeeded in protecting rhesus monkeys against Plasmodium knowlesi using non-viable fractions extracted from disintegrated parasites. This and earlier studies, taken together, have shown that eleven out of seventeen vaccinated monkeys survived challenge whereas eight controls did not. Both these kinds of approach obviously have some potential promise but they still need a considerable amount of development.

The most promising vaccination results so far achieved with monkeys are reported in this issue of Nature by Mitchell, Butcher and Cohen from Guy's Hospital Medical School. They used Plasmodium knowlesi and their vaccine consisted of emulsified cultured merozoites. Six monkeys were immunised in various ways and challenged some time later with the homologous parasite or heterologous variants. Protection against the homologous parasite was absolute in two monkeys and strong in the third. There was also considerable protection against heterologous variants and the parasitaemias never rose above 1.5% whereas control animals died after about a week. Subsequent challenges with other variants resulted in equally encouraging results. The merozoite vaccine was found to be species specific and afforded only minimal protection against challenge with Plasmodium cynomolgi bastianellii.

These results show that the merozoite vaccine induces immunity better than that obtained after repeated challenges and cures. This contradicts the belief that vaccination against malaria cannot induce an immunity better than that which can be acquired naturally. The fact that the immunity induced transcends challenge with several variants suggests that the antigenic variation that occurs in malaria is not an insuperable barrier to vaccination, as has already been shown by Clyde and his co-workers. Of particular interest is the fact that the merozoite vaccine is simple to prepare and that 1 ml of parasitised blood cells provides twenty

immunising doses. These are early days yet and the next step will have to be the evaluation of the merozoite vaccine in owl monkeys, which are the only suitable primates that can be infected with human malaria. These monkeys are becoming increasingly difficult to obtain as thousands have been used for testing drugs. Very soon malariologists will have to draw up priorities for the use of owl monkeys and the whole drug/vaccine argument will have to be thrashed out afresh.

# Messenger RNA doing without poly(A)

One of the tenets of cell biology has been that all messengers in the cytoplasms of eukaryotic cells (with the sole exception of the histone mRNAs) contain a length of poly(A), which fulfils some essential, although as yet unidentified function. When polysomal mRNA is examined for poly(A) content by reaction with poly(U)-sepharose or oligo(dT)-cellulose, most is bound; the fraction that is not retained has generally been thought to result from breakages in mRNA during isolation-since there is only one length of poly(A) in each mRNA, a single breakage would release a molecule altogether lacking poly(A). In two quite different systems, however, it now seems that an appreciable proportion of the cellular mRNA may lack poly(A). Working with HeLa cells, Milcarek, Price and Penman (Cell, 3, 1-10; 1974) find that about 30% of the mRNA lacks poly(A); and using early sea urchin embryos of two species (Strongylocentrotus purpuratus and Lytechinus pictus), Nemer, Graham and Dubroff (J. molec. Biol., 89; 1974) report that about 40% of the messages may lack poly(A).

To examine mRNA of HeLa cells, it is necessary both to prevent labelling of ribosomal RNA and also to exclude contaminants derived from the non-messenger RNA population. The second can be achieved by releasing mRNA from polysomes with EDTA and in these experiments the first condition was met by using fluorouridine to suppress labelling of rRNA. The labelled mRNA fraction was then passed through a column of oligo(dT)-cellulose under conditions in which more than 96% of the poly(A)-containing mRNA is retained. This divides the mRNA into a major (70%) fraction containing poly(A) and a minor (30%) fraction apparently lacking it. Both poly(A)+ and poly(A)mRNA have the same size distribution. That both classes of mRNA are in use in the HeLa cell as templates for protein synthesis is suggested by the use of puromycin, which releases both from the polysomes.

Only the demonstration that the nucleotide sequences of poly(A)<sup>+</sup> and poly(A)<sup>-</sup> mRNA fractions are different can provide satisfactory evidence that they represent two genuine cellular species and that the poly(A)<sup>-</sup> is not in fact derived from the poly(A)<sup>+</sup>. The sequences of the poly(A)<sup>+</sup> mRNA can be scrutinised by production of a complementary cDNA probe through the reverse transcription mediated by the enzyme of RNA tumour viruses; and in hybridisation

## What controls rates of evolution?

Ever since the pioneer work of G. G. Simpson some three decades ago it has been recognised that one of the most important contributions that palaeontology can make to our knowledge and understanding of evolution is in determining rates of morphological change for different fossil groups over long periods of time. Simpson was the first to bring comparative quantitative data to bear on this subject, and convincingly demonstrated that, in terms of rates of origination and extinction, and of structural innovation, the mammals easily led the field. Van Valen has now endeavoured to show, in a letter published on page 298 of this issue, that whereas in general mammals have evolved at a faster rate than other organisms, there are at least two types of evolution in which the rate is effectively the same, namely the rate of amino acid substitution in proteins and change of size measured linearly. The first type of evolution is termed the epistandard, the other the standard mode.

Van Valen attempts a tentative explanation of the epistandard mode in terms of his Red Queen hypothesis, which is spelled out fully in an earlier paper (Evolution Theory, 1, 1; 1973). Readers of Through the Looking Glass will recall that the Red Queen explained to Alice that it took all the running one can do to stay in the same place. Van Valen put forward his hypothesis in an attempt to explain why the probability of extinction of fossil groups was more or less constant in time. It is based on the idea that all species within a given adaptive zone compete intensively. A successful adaptive response by one species is assumed to occur at the expense of other species, which must either adapt by themselves speciating or become extinct, as the 'quality' of their environment is reduced. This phenomenon leads to an endless chain of adaptive responses and in the long run

means that fitness and rate of extinction remain constant.

The high rate of diversification and evolutionary turnover in mammals is likely to be the result of a variety

of factors, such as strong competitive interactions leading to specialisation in feeding methods, limitations on food supply, high mobility and energy use, interspecies aggression and territoriality. Such factors will conspire to lower the 'resource threshold' needed to prevent extinction, compared with other animals. Epistandard rates are required to make up the losses through extinction.

Though the Red Queen model might apply well to mammals, there are doubts about its more general validity. This is brought out well, for instance, in a thoughtful paper by Stanley (Systematic Zool., 22, 486; 1973), who analyses the effects of competition on evolutionary rates. Attention is confined mostly to the mammals and the bivalve molluscs (that is, clams and oysters). In sharp contrast to mammals, the bivalves are nearly all sea-bed suspension feeders which mind their own business, characterised by weak interactions with other species, primitive inflexible behaviour, uncrowded, largely sedentary mode of life and generalised feeding habits.

This has as a direct consequence substantially lower rates of evolution than mammals, as Stanley amply documents. Limits on the bivalve populations are imposed more by predation and fluctuations in the physical environment than by food resources, and biological competition is minimal. As Stanley observes laconically, "Interspecific aggression is not characteristic of bivalve behaviour". What is true of bivalves is without much doubt true of the majority of benthonic invertebrates. Through the Looking Glass might be less appropriate as a textual source for the relevant evolutionary sermon than The Walrus and the Carpenter.

A. HALLAM

experiments, the cDNA anneals back to its poly(A)<sup>+</sup> mRNA template, but does not react with the poly(A)<sup>-</sup> mRNA until much higher  $R_0t$  values are reached (and perhaps only then because of the presence of contaminating poly(A)<sup>+</sup> mRNA in the poly(A)<sup>-</sup> fraction). Because the cDNA represents only the 500 or so bases at the 3' terminal end of the messenger, immediately adjacent to the poly(A), the hybridisation analysis does not in itself exclude the possibility that the poly(A)<sup>-</sup> mRNA represents 5' ends broken off poly(A)<sup>+</sup> messengers; but this is rendered rather unlikely by the observation that poly(A)<sup>+</sup> and poly(A)<sup>-</sup> messengers are of the same size.

A similar situation is found in early sea urchin embryos, in which the sequences present in the poly(A)+ and poly(A)mRNA fractions were investigated by preparing a cDNA from the poly(A)+ mRNA by using the DNA polymerase I enzyme of Escherichia coli. At the maximum  $R_0t$  values reached, some 80% of this cDNA annealed with the poly(A)+ mRNA; the low level of reaction with the poly(A) mRNA shows that this fraction is almost entirely constituted of sequences different from those present in the poly(A)+ mRNA class. From the hybridisation reaction between the cDNA and poly(A)+ mRNA, it is possible to calculate that the complexity of the poly(A)+ mRNA corresponds to about 1,400 different species, each present on average 10,000 times in the embryo (which at this stage corresponds to about 400 cells). The complexity and abundance of the poly(A) class cannot be estimated since no probe for its sequences has been developed. Since the earlier work of Galau et al. (Cell, 2, 9-22; 1974) showed that the total polysomal mRNA falls into two abundance classes at the 600 cell stage, with less than 10% of the

mRNA representing 14,000 sequences present on average 340 times in the embryo, while most of the mRNA represents a much smaller number of sequences present in many copies each, it is of obvious importance to define the complexity of the poly(A)<sup>-</sup> mRNA and to see how the total messenger population is divided into classes containing and lacking poly(A).

Only the histone messengers previously have been shown to lack poly(A), a feature which it was thought might be related to their synthesis during only part of the cell cycle; and also which it seemed possible might be responsible for their rapid appearance in the cytoplasm after addition of a radioactive label—the delay in appearance of a label in poly(A)+ mRNA might be due to the time involved in addition of poly(A). The kinetics of production and decay of the poly(A)+ and poly(A)- mRNA classes in the HeLa cell, however, seem to be indistinguishable, so that whatever mechanism is used to produce the poly(A)" class does not promote a more rapid cytoplasmic transport. Nothing is known yet about the mechanism of production of poly(A) messages, whether a large precursor is involved as seems to be the case with poly(A)+ mRNA or whether some different mechanism is implicated. The existence of poly(A) mRNA, however, appears to argue against models which suppose that the addition of poly(A) provides the only mechanism by which messengers are recognised for transport to the cytoplasm; and also raises the question of what function the poly(A) may play in the cytoplasmic activities of the messengers containing it. The purpose of poly(A) is therefore now less clear than

BENJAMIN LEWIN

# Alpha-particle transfer

from P. E. Hodgson

Nuclear reactions in which a nucleon or group of nucleons are transferred from the incident particle to the target nucleus are one of the most fruitful sources of information about nuclear structure. Single-nucleon transfer reactions have been extensively studied and have provided detailed information about the single-particle states of nuclei. The mathematical description of such processes is much more complicated when several particles are transferred, but already much work has been done on two-nucleon transfer reactions. Reactions in which an alpha particle is transferred are also being extensively investigated, and since the alpha particle is tightly bound it is sometimes a good approximation to treat it as a single particle and to use the formalism of single-particle transfer reactions.

Nuclear reactions initiated by heavy ions often show simple features that can be quite well understood by a semiclassical theory. Thus we can think of the incident particle following a definite orbit as it is scattered by the target nucleus, as a comet is deflected by the gravitational field of the Sun. If a transfer of nucleons takes place it naturally does so when the orbit of the incident particle is nearest the surface of the target nucleus (see Fig. 1).

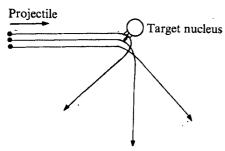

Fig. 1 Sketch showing the relations between the impact parameters, the scattering angles and the probability of a reaction taking place for several different classical orbits.

If now we consider such classical orbits of steadily decreasing impact parameter (the distance of the closest approach in the absence of a deflecting field) we can easily see that those with large impact parameters pass so far from the nucleus that a transfer reaction is very unlikely. Since these orbits are not strongly deflected, the cross section for particle transfer is small for small scattering angles. As the impact parameter is reduced the scattering angle increases and the orbit approaches nearer to the nuclear surface, increasing the likelihood of a transfer reaction. Thus the cross section of the transfer reaction initially

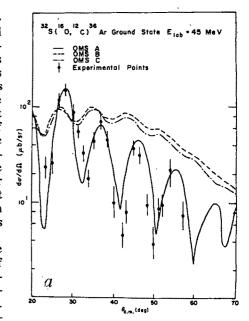

increases as the scattering angle increases. This increase continues until the orbit just touches the nuclear surface, and in this case the transfer is most likely. If the impact parameter is still further reduced the orbit cuts through the nucleus and the projectile interacts so strongly with the target nucleus that a very large number of reactions can take place and the probability of the simple transfer reaction falls. Thus on the simple classical picture we expect the transfer reaction to have a cross section that first rises to a maximum and then steadily falls as the scattering angle is

Such bell-shaped cross sections have frequently been found in studies of heavy ion transfer reactions, and semiclassical calculations give good agreement with the experimental data. These calculations are called semiclassical because the projectile is assumed to move along a classical orbit in the field of the target nucleus, but the actual transfer process is treated quantum-mechanically.

A fully quantum-mechanical theory of these reactions has also been developed, and it is known as the distorted wave theory. The interacting particles are represented by wave functions, and the way they are distorted by the field of the target nucleus is found by solving the appropriate Schrodinger wave equation. Such calculations also give the bell-shaped curve, and also some of the details of the cross sections that are not given by the classical theory (see *Nature*, 246, 334; 1973).

Last year the differential cross section of the alpha-particle transfer reaction <sup>22</sup>S(<sup>16</sup>0, <sup>12</sup>C)<sup>36</sup>Ar was measured by Braun-Munzinger and colleagues in Heidelberg (*Phys. Rev. Lett.*, 31, 1423; 1973) and they found that contrary to expectation it has a strongly oscillatory structure, as shown in Fig. 2. Calculations of the cross section of this reaction gave the usual bell-shaped curve, so it was an important challenge to try to understand the origin of the pronounced oscillations that were observed experimentally.

Charlton and Robson (Phys. Rev. Lett., 32, 946; 1974) tackled this problem and found that if it was assumed that the transferred alpha particle was in its  $2^+$  state at 28.5 MeV an oscillatory angular distribution is obtained, in good overall agreement with the experimental data. Although this process may seem somewhat unplausible physically due to the high excitation energy required, detailed nuclear structure calculations showed that the probability of the dissociation  ${}^{36}A \rightarrow {}^{32}S + \alpha^*$ , where  $\alpha^*$  stands for the excited alpha particle, is such that the transfer for the excited alpha particle

is about five times more likely than transfer in its ground state.

Additional studies of this reaction have recently been made by Werby and Tobocman (Phys. Rev., C10, 1022; 1974) and they investigated in detail the effect on the cross section of varying the potential that represents the interaction between the incident particle and the target nucleus. This is in fact not known very well, and what is usually done is to assume that it has the form of an optical model potential and to adjust its parameters to give a good fit to the differential cross section for the elastic scattering interaction, when the incident particle is simply deflected without losing energy or nucleons. Unfortunately the potentials found in this way are not

unique, and it is possible to find several sets of parameters that give equally good fits to the elastic scattering data. This is particularly so at low energies where the elastic scattering cross section is rather featureless, as is the case for the reaction of interest here.

Werby and Tobocman found several quite different potentials that all give acceptable fits to the elastic scattering, as shown in Fig. 3. The first of these labelled A has an absorbing potential of only 6 MeV, much less than the 30 MeV used by Charlton and Robson; all the parameters of these potentials are given in the table.

The cross sections for the alphatransfer reaction calculated with these potentials using the distorted wave theory are shown in Figure 2a, and it is immediately evident that the strongly absorbing potentials give curves with weak oscillations that have the overall bell shape characteristic of the classical case, while the weakly absorbing potential A gives a strongly oscillating curve that agrees very well with the experimental data. Since these calculations assumed that the transferred alpha particle is in its ground state, it is not necessary to postulate the transfer of excited alpha particles in order to obtain a good fit to the data.

These results all refer to the reaction that leaves the residual nucleus <sup>36</sup>A in its ground state. Experimental data are also available for the same reaction to the first excited state, and the corresponding measured and calculated cross sections are shown in Figure 2b. The experimental cross sections again show an oscillatory structure, though it is not so marked as for the reactions to the ground state, and once again the strongly

absorbing potentials give a featureless bell-shaped curve while the weakly absorbing potential gives an oscillatory cross section in qualitative accord with the data.

It is interesting to try to understand just why the weakly absorbing potential gives an oscillatory cross section while the strongly absorbing potentials do not. This can be done by examining the details of the formalism of the distorted wave theory, in particular the contributions of the different partial waves to the reaction amplitude. It is found that relatively few partial waves contribute, especially when there is no angular momentum transferred in the reaction, as is the case for the present reaction to the ground state of 36Ar. Now the contribution of a particular partial wave depends on an integral of the products of the radial parts of the distorted waves of the incident and outgoing particles and a form factor depending on the positions in space of the colliding particles. The value of this integral depends on the potentials chosen, and then what determines the overall features of the cross section is the way the phase of the integral varies from one partial wave to the next for the important partial waves. It is found that for the weakly absorbing potential A the phase remains fairly constant in this region, giving constructive interference between the integrals for the different partial waves. For the strongly absorbing potentials B and C, however, the phase of the integral changes rapidly and produces destructive interference in the critical region. This difference in the behaviour of the integrals is responsible for the difference in the cross sections corresponding to the two types of potentials.

In the case of the reaction to the first excited state of <sup>36</sup>A, two units of angular momentum are transferred and this increases the number of partial waves that contribute significantly to the interaction. This has the effect of reducing the amplitude of the oscillations, but the qualitative explanation of the difference between the cross sections calculated with the two types of potentials is still valid.

It should be noted that the calculated cross sections in Fig. 2 have been normalised to the experimental data. The value of the normalisation factor depends on the product of the spectroscopic amplitudes for the dissociation

of the incident <sup>16</sup>O into <sup>12</sup>C+ the combination of α and <sup>32</sup>S t <sup>36</sup>A. If excited alpha particle also transferred the amplitudes for corresponding dissociation and bination have also to be include the calculation. At present the nucleus tructure part of the process is understood sufficiently well for relia quantitative calculations to be making and it will be a critical test of such calculations to see if they give the measured values of the cross sections.

It is clear that in spite of consider able progress there is still much to be learnt about the mechanism of these alpha-particle transfer reactions. We do not know what potential to use for the interaction between the incident particle and the target nucleus, and it is likely that further progress will come from the many attempts that are now being made to calculate the potential from a detailed theoretical model of the interaction, instead of the phenomenological approach used in the present calculations. It is clear that the elastic scattering alone does not determine the potential accurately enough, but studies of reactions such as those described here enable it to be more precisely defined. Thus it may be that studies of a wide range of reactions will also give more reliable potentials. On the nuclear structure side there is also much work to be done, and this should enable the relative contributions of unexcited and excited alpha-particle transfers to be evaluated.

The present situation for these reactions frequently occurs in nuclear reaction calculations. At first there is a strange cross-section that disagrees with existing calculations. Then a new model is developed that seems to explain the results, until it is found that several different models all do equally well. At this stage it is necessary to probe deeper and try to understand what is going on in a very detailed way, so as to distinguish between the merits of rival models.

# Movement of auxin across plant cell membranes

from our Plant Cell Physiology Correspondent

Auxins stimulate the extension fowth of plant cells. They are synthes d in the shoot apex and regulate the pansion of cells below the tip. Studies with the naturally occurring auxin indole acetic acid (IAA) and the synthetic analogue 2,4-dichlorophenoxy-acetic acid (2,4 D) have shown that these compounds move preferentially from the apex towards the base of plant stems. This process is often referred to as

'active transport' because it requires energy, and the movement of applied auxin from base to apex of stem segments is extremely low by comparison. The continued production and export of auxin from the shoot tip is thought to be responsible for such phenomena as the inhibition of outgrowth of lateral buds by the apex and the control of adventitious root production at the base of cut stems. For these reasons studies on the polar transport of auxin and the mechanism of auxin movement across the plasmalemma are of considerable interest.

Recent experiments by Rubery and Sheldrake carried out in the University of Cambridge have shown that there are at least two different mechanisms for the passage of auxin across membranes and that 'secretion' of auxin from cells may not be driven directly by the hydrolysis of ATP but rather may depend upon the pH gradient across the membrane (Planta, 118, 101; 1974).

Rubery and Sheldrake used crown gall cells of Virginia creeper grown in suspension culture as a model system to study auxin influx and efflux under a variety of experimental conditions. (Unlike most cultured plant cells crown gall cells do not require an exogenous supply of auxin in order to grow.) In a previous paper (Rubery and Sheldrake, Nature new Biol., 244,

288; 1973) it was shown that with the external medium at pH 4.3, when IAA is only slightly ionised (pK=4.7) there is a linear relationship between IAA uptake and the external concentration up to 500 µM IAA. Under these conditions it is assumed that the undissociated IAA, which is lipid soluble, enters the cells by diffusion. Once inside the cells where the pH of the cytoplasm is above pH 7, IAA would be expected to ionise, thus maintaining a concentration gradient for the passage into cells of undissociated IAA by diffusion. The authors now suggest that a passive anion carrier also operates between pH 5 and pH 6.7. The optimum for the anion carrier is about pH 6 and the carrier is apparently half saturated at quite low IAA concentrations within the range 1-5 μM. The carrier is capable of bringing about either the influx or efflux of IAA anions depending upon the direction of the concentration gradient. Studies on the operation of the carrier system were greatly aided by the observation that 2,4 D inhibits the carrier-mediated IAA anion influx and that 2,3,5-triiodobenzoic acid (TIBA), a known inhibitor of polar auxin transport, prevents the efflux of anions but has no effect upon the entry of IAA anions into cells. These results suggest that the properties of the carrier are different on the inside and outside of the plasmalemma and that 2,4 D binds to the carrier at the external face and TIBA binds at the internal face of the membrane. The apparent specificity of TIBA in inhibiting anion efflux is very interesting because it has been known for some time that in shoot segments TIBA inhibits polar auxin transport by interfering specifically with the exit of

IAA from the cells. Rubery and Sheldrake point out that if an auxin carrier similar to the one that operates in crown gall cells is localised in the membrane at the basal end of the cells in plant shoots, this would provide a mechanism for the observed polar transport of IAA. When the pH within the cell walls is acidic, auxin will enter the cells by diffusion and accumulate there. Eventually the internal anion concentration will rise above that outside the cell and the carrier will mediate the efflux of IAA anions across the membrane at the base of the cell into the cell wall. Providing the pH within the wall is lower than that of the plant cytoplasm some of the auxin will then enter the adjacent cell by diffusion where it will again be carried across the basal membrane as IAA anions. The net result of this process is polar auxin transport. Although ATP is not required to drive the secretion of IAA across the plasmalemma there is an indirect requirement for energy in order to maintain

### Density of galactic space

from David W. Hughes

THE mean density of space in the solar region of the Milky Way galactic plane is an important astrophysical quantity. First it is a fundamental parameter in the study of galactic dynamics and second it gives a lead to the way in which the galactic material is proportioned out between stars, gas and dust.

By studying the variation of galactic rotation as a function of distance from the nucleus Schmidt (Galactic Structure, University of Chicago Press, 1965) calculated that the total local mass density near the Sun should be  $0.14 M \odot \text{ pc}^{-3}$ , where  $M \odot$  is the solar mass  $(2 \times 10^{33} \text{g})$ and a parsec is 3.08×1018 cm. This is equivalent to  $1 \times 10^{-23}$ g cm<sup>-3</sup>. A similar value (~ 0.20 M ⊕ pc<sup>-3</sup>) was required by Oort (ibid.) to account for the observed stellar velocities perpendicular to the galactic plane. A problem immediately arose because the densities of stars, dust and gas in the vicinity of the Sun only added up to  $0.084 M_{\odot} \text{ pc}^{-3}$  indicating either that the estimates of the individual densities were wrong or that the Galaxy contains some mysterious mass in the form of unobserved objects.

Luyton (Mon. Not. R. astr. Soc., 139, 221; 1968) calculated how the number of stars in regions of the Milky Way vary as a function of their luminosity, and using the mass-luminosity relationship found the stellar mass density to be 0.064 M ⊙ pc<sup>-3</sup>. The interstellar dust in the Galaxy can be detected by looking at the extinction of stars as a function of distance, the reddening of starlight that passes through dusty regions, the polarisation of starlight by intervening dust and finally by observing the diffuse galactic light. The mean density of

this dust is found to be  $0.0015\,M_{\odot}$  pc<sup>-3</sup>. Interstellar gas produces atomic and molecular absorption lines in stellar spectra and also radiates emission lines in the microwave radio region of the electromagnetic spectrum. Measurements of these lead to a mean gas density of  $0.018\,M_{\odot}$  pc<sup>-3</sup>.

The missing mass problem was partially solved in 1972 by Weistrop (Astronomical Journal, 77, 849; 1972) who found that a substantial number of red dwarf stars had been overlooked previously and also that these stars are strongly concentrated towards the galactic plane. Weistrop's observations led to a 100% increase in the stellar mass density which then became  $0.13 M_{\odot}$  pc<sup>-3</sup>.

Glenn Veeder (Hale Observatories, California Institute of Technology) in a recent letter to the Astrophysical Journal (191, L57; 1974) has calculated a revised empirical relationship between the absolute visual magnitude of a star and its mass, this coming from observations of low-mass faint multiple stellar systems. Veeder finds that the main-sequence stellar mass density in the solar neighbourhood is now  $0.16 M_{\odot}$  pc<sup>-3</sup>. Add to this the mass contribution due to dust and gas and the density becomes  $0.18 M_{\odot}$  pc<sup>-3</sup> with the material divided between stars, gas and dust in the percentages 89, 10, 1.

So the missing mass of 1965 has now been found and the results of the galactic dynamicists and the stellar astronomers agree within the expected margin of error. This also means that unobserved objects (black holes, dead white dwarfs and so on) must only make up a non-significant percentage of the galactic mass.

the pH of the cytoplasm above that in the walls. Providing that this requirement is met, the specificity of the transport system would reside in the preferential distribution of IAA anion carriers in the basal membranes of the cells. It is possible that an alteration in the distribution of the carrier might also explain the lateral movement of auxin observed during tropic responses.

# Indicators of palaeoseismicity

from Peter J. Smith

DETERMINATION of the ancient geomagnetic field may be fraught with practical difficulties, but palaeomagnetists do at least have access to abundant material in which the field is recorded. Seismologists, by contrast, are less fortunate. Insofar as they are concerned with using seismic waves to investigate the Earth's internal structure and properties, they must be content with the Earth as it is today; in this sense there is no such thing as palaeoseismology. But it is possible to envisage the study of palaeoseismicity; and this branch of seismology already exists in a limited way. It is clear from plate tectonics, for example, that the bulk of the world's current seismicity coincides with the three types of plate boundary. And as the reasons for this correlation are broadly understood, it may reasonably be inferred that the association has always obtained. In principle, therefore, it should be possible to define the location and timing of palaeoseismicity by finding and dating ancient plate bound-

But this is a very general approach, equivalent in palaeomagnetism to defining when and where the Earth had a magnetic field. Is it possible to be more specific? Is there some phenomenon which could be used to determine the details of ancient seismicity or even the characteristics of individual seismic events, rather as rock magnetism may be used to determine the details of the ancient magnetic field? So far there is no known phenomenon which may be used to investigate palaeoseismicity in a routine way; but a hint that such investigations may ultimately be possible in certain situations has now come from Engelder (J. geophys. Res., 79, 4387; 1974) who has been studying the microscopic effects on surfaces which have slid against each other.

Engelder's suggestion is based on both laboratory and field studies. In the laboratory experiments, polished samples of Westerly granite were slid against each other for distances up to 3 mm and under confining pressures up to 2.9 kbar. At pressures below 0.3 kbar, stable sliding occurred with no damage to the polished surfaces. But at higher pressures stick-slip took place, producing wear grooves, scratches and small climps of gouge on the surfaces. Of particular interest are the wear grooves which are generally carrotshaped with the tip pointing in the direction of motion of the surface containing the grooves. The amount of slip can be calculated from the lengths of the grooves, for each event produces grooves with various lengths up to the distance of the slip (that is, groove lengths are not related to the total amount of slip where a series of individual slips is concerned but only to the distances of the individual slips themselves).

In the field, Engelder has found two natural counterparts to these experimental systems. The first is a slickenside (polished surface resulting from friction along a fault plane) in the Mesa Rica sandstone in the Bonita normal fault zone of New Mexico. In this case the longest of the carrotshaped grooves are 5 mm long. Unfortunately, the total slippage during the formation of this slickenside is not known, so it is impossible to say whether the grooves were produced during a single slip event or during a series of events, although the grooves do point in the known direction of motion. In the second example, a slickenside in Tintic quartzite in the Eureka fault zone of Utah, neither the sense nor the total amount of slip is known. But if Engelder is right, the sense of slip may now be deduced from the grooves. Moreover, as the longest grooves here are 0.5 mm and as 0.5 mm of slip is insufficient to generate highly polished slickensides in quartzose rock, it may be concluded that more than one slip event, and probably such events, took place.

From the morphology and lengths of those natural and experimental grooves it is possible to deduce a mechanism for their formation. In simple terms, what apparently happens is that, at the initiation of a slip, interlocking asperities (which previously prevented slip) shear. As the slip progresses, other asperities (and gouge particles) gradually plough deeper into the opposite surface, forming grooves which gradually widen (as viewed in section) and slowing down the slip until it finally stops. The cycle is then repeated, beginning again with the shearing of asperities. If the asperities did not shear at the start of each slip but instead jumped out of their old grooves and ploughed new ones, a series of inline grooves would be formed. These are seldom observed. If, on the other hand, asperities failed to shear but instead continued to plough the old

grooves, grooves would general longer than one slip length Than seldom observed either. What are served, however, are some two which are shorter than one slip corresumably because not all as cobegin to plough at the start of a

Because Engelder is here coally microscopic features, the common with palaeoseismicity is not discription tis, however, that some so is clearly related to stick-sip. Moreover, the mechanism summa above closely resembles one preceded put forward to explain macroscopic stick-slip behaviour. The question to Engelder poses is thus: is there to some preceded planes that may be used for fixing planes that may be used for fixing guishing seismic from ascismating the amount of during seismic events?

For the time being, the case of cannot be answered. But if such that as are found, Engelder's work, albeit on a microscopic scale, suggests tha trey could give a significant boost to be study of palaeoseismicity Aki () " Earthquake Res. Inst., 44, 73, 19:65 for example, has proposed a ferr la for calculating an earthquake's relative moment from the average displacement of one slip on the fault, a ferrilla which Engelder uses to determine the moment of an event along th. ... fault zone. A similar calcula i be carried out for macroscop. along large faults, although in . . . of such a scaling-up would f to be tested rigorously.

# Cattle help in conservation

from Peter D. Moore

Although conservation has come to mean much more than the simple preservation of rare species, the prevention of extinction of threatened plants and animals is still an important concern of the conservationist. Apart from the possibility of aesthetic loss (consider how great a contribution the giant panda has made to the fantasy worlds of our children), a depletion of the planet's genetic resources accompanies each extinction which may ultimately be regretted even by those who have lost their aesthetic awareness. A good example of a lowly plant made rare by the destruction of suitable habitats and which has received such attention from conservationists is Dianthus armeria, the Deptford pink, which is restricted to a few meadows in southern Britain (see Walls, Proc. Bot. Soc. Br. Isl., 6. 337; 1967).

One of the sites at which this species occurs is Woodwalton Fen, a National Nature Reserve in the fenland area of East Anglia. Most of this nature reserve has been managed by man in the past, either for reed cutting, peat extraction or as grazing land; the area with Dianthus armeria was once a farmstead over which cattle were grazed. This practice was not continued in the early days of the reserve's history, but locally the pressure of rabbit grazing was sufficient to maintain the shortgrass community in which Dianthus survived. Following the myxomatosis epidemic of 1954, however, extensive changes occurred in the vegetation of the area; coarse grasses, particularly Calamagrostis epigejos and Agropyron repens, spread at the expense of shorter-growing species, including Dianthus. By 1964 only five plants remained and at this stage a new management regime involving grazing by Friesian heifers was introduced. Subsequently the population of *Dianthus* expanded gradually to 900 plants by 1967.

Williams, Wells and Wells (J. appl. Ecol., 11, 499; 1974) have now attempted to analyse the respective roles of cattle and rabbit grazing in this particular recovery. They undertook a quantitative analysis of the faeces of these animals by concentrating the surviving plant epidermal fragments in a faecal sample and spreading them on a microscope slide. The species composition of these samples was subsequently estimated by means of randomly located point observations. This type of analysis was repeated periodically through the course of a year in order to determine the changing food preferences of the animals during that time. As Stewart (J. appl. Ecol., 4, 83; 1967) has pointed out, there are many problems associated with this technique, particularly the relative digestibility of different species. But the preponderence of coarse grasses in the cattle faeces and the virtual absence of dicotyledonous species gives a reasonable representation of this animal's diet. The rabbits also seem to have neglected dicots, but show a stronger preference for the less coarse grasses, such as Festuca.

The results of these studies suggest that the beneficial effect of cattle upon the Dianthus armeria population results from their selective grazing upon the more aggressive species of grass. The techniques employed however, do not permit conclusions regarding the influence of trampling upon Dianthus by increasing microtopographical diversity. When scarce, the plant became restricted to ant hills, which suggests that soil disturbance and microtopographical factors may be important in controlling its distribution. Examination of the germination and establishment requirements of Dianthus under laboratory conditions might assist in the separation of these two distinct influences of cattle grazing. Meanwhile it cannot be denied that this is an efficient management practice for the conservation of a diminishing species.

discussion that these fears have been exaggerated.

Recent work on the genetic basis of Xeroderma Pigmentosum have shown the value of studies of heterokaryons formed by fusing fibroblasts from patients with the disease and from normal subjects. Dr P. Lohman (Netherlands Organisation for Applied Scientific Research, Rijswijk) reported that there are now five complementation groups in Xeroderma Pigmentosum. Dr Lohman also discussed experi-

ments which showed that ultraviolet-irradiated chicken fibroblasts can repair DNA damage other than that involving pyrimidine dimers. Investigations by Dr F. Giannelli (Guy's Hospital Medical School, London) indicate that the enzyme which is defective in most patients with Xero-derma Pigmentosum is probably not a monomer. In addition, it is possible to detect heterozygotes for Xeroderma Pigmentosum mutations by the assessment of DNA repair in heterokaryons.

The past few years have seen the emergence of Xeroderma Pigmentosum variants, patients with clinical features of the disease but with normal ability to carry out excision repair of DNA. Dr A. Lehmann (University of Sussex) has recently confirmed that in these patients all of the steps in excision repair are normal, but that there is a defect in post-replication repair. Post-replication repair in Xeroderma Pigmentosum variants is inhibited by caffeine, an effect which is not present in normal cells. Cells from patients with Xeroderma Pigmentosum who are defective in excision repair show changes in post-replication repair which are intermediate between normal and Xeroderma Pigmentosum variants.

Another aspect of this disease was discussed by Dr C. A. Ramsay (Institute of Dermatology, London). He demonstrated the abnormal reactions of the skin of these patients when they are irradiated with monochromatic ultraviolet light in the 290-320 nm region. The delay in the onset of erythema after irradiation may enable the diagnosis of Xeroderma Pigmentosum to be suspected early in life. In addition, Dr Ramsey reported the first successful case of the prenatal diagnosis of Xeroderma Pigmentosum by the detection of the deficiency of excision repair in cultured amniotic cells. Xeroderma Pigmentosum is the only condition to date in which excision repair of DNA has been found to be abnormal. Actinic keratoses occur on normal skin as a result of chronic exposure to solar ultraviolet irradiation and Dr J. Pitts (University of Glasgow) has found that in cells of such keratoses excision repair is not impaired.

Several other aspects of photosensitive skin disease were discussed. A review of the value of action spectroscopy in dermatology was given by Dr Frain-Bell (University of Dundee). The photodermatoses present many unsolved problems not least of which is that of treatment. Dr J. C. van der Leun (State University of Utrecht, Netherlands) has used the technique of repeated irradiation of the skin as a method of treatment and has found it of benefit in solar urticaria and polymorphic light eruption. These findings are of interest because the two diseases represent quite different reactions to sunlight; solar urticaria occurs very soon after irradiation whereas in polymorphic light eruption there is a delay of several hours before the skin changes

Finally, a detailed study of the photochemical basis of a dye-induced photodermatitis was reported by Dr K. Davies (University of Salford). He showed that in this reaction with an antraquinone dye, singlet oxygen is an important intermediate.

# Do machines understand more than they did?

Yorick Wilks\*

To be able to communicate in ordinary English, a machine must have access to common sen information about the real world. The first computer systems to attempt such communication lived very limited worlds. Now, with a "second generation" of programs, those worlds are widening although the exact significance of the recent advances is still in dispute.

In his report to the Science Research Council on the state of artificial intelligence (AI), Sir James Lighthill¹ gave most of the field a rather bad prognosis. One of the few hopeful signs he saw was Winograd's computer system for natural language understanding². Yet now, only a year later, Winograd has stopped work on the system he constructed, and has begun a new one on entirely different principles. He went so far, in a survey lecture (Third International Joint Conference on Artificial Intelligence, Stanford, California, 1973) of extraordinary modesty in a field not known for its small claims, to place his celebrated early work in only the "first generation" of computer systems designed to understand natural language, before going on to describe others' "second generation" systems.

I shall return later to this metaphor of generations, but what is one to say in general terms of a field where yesterday's brightest spots are today's first generation systems, even though they have not been criticised in print, nor shown in any generally acceptable way to be fundamentally wrong? Part of the answer lies in the profound role of fashion in artificial intelligence in its present prescientific phase. A cynical American professor remarked recently that AI had an affair with someone's work every year or two, and that, just as there were no reasons for the falling in love, so, later, there were no reasons for falling out again. In the case of Winograd's work it is important now to resist this fashion, and re-emphasise what a good piece of research it was, as I shall show in a moment.

Another part of the answer lies in the still fundamental role of metaphysical criticism in AI. In the field of computer vision things are bad enough, in that anybody who can see feels entitled to criticise a system, on the ground that he is sure that his own vision is not based on the same principles. In the field of natural language understanding things are worse: not only does anyone who can speak and write feel free to criticise on the corresponding grounds, but those trained in disciplines parasitic upon natural language, linguists and logicians, often have strong views on a priori grounds on how things must be done. It is this metaphysical aspect of the subject that gives its disputes their characteristically acrimonious flavour.

In this article I want to sort out a little what is agreed and what is not; what are the outstanding disputes and what are the systems making the most testable claims. If what follows seems unduly philosophical, it should be remembered that little is agreed, and almost no achievements are beyond question. To pretend otherwise, by concentrating only on the details of established programs, would be meretricious and misleading.

#### Winograd's understanding system

Winograd's system runs as a dialogue, in real time, between a human operator who types in messages, and the system proper,

\* Artificial Intelligence Laboratory, Stanford University, California 94305; present address: Fondazione Dalle Molle, Villa Heleneum, 6976 Castagnola, Switzerland.

called SHRDLU, which displays on a screen pictures of a closed world of coloured blocks and pyramids, a box into which they can be put, and an arm or crane that can move the objects about. SHRDLU displays its replies to the operator by writing on the same screen. The following is a discontinuous sample of the dialogue Winograd gives in his book. SHRDLU's replies are in upper case:

pick up the big red block

OK

find a block which is taller than the one you are holding and put it into the box.

BY 'IT', I ASSUME YOU MEAN THE BLOCK WHICH IS TALLER THAN THE ONE I AM HOLDING

OK

what does the box contain

THE BLUE PYRAMID AND THE BLUE BLOCK

had you touched any pyramid before you put the green one on the little cube

YES, THE GREEN ONE

when did you pick it up

WHILE I WAS STACKING UP THE RED CUBE, A LARGE RED BLOCK AND A LARGE GREEN CUBE

why

TO GET RID OF IT.

This ingenious program was also able to accept new definitions of words, such as "steeple"; to make use of what it knew about the properties of the objects described, such as that a block could have its top cleared off, but a pyramid could not; and also to remember what it had done before, as in the sample above.

The program was written in the language PLANNER<sup>3</sup>, which is the concrete expression of the slogan "meanings are procedures", a sentiment into whose own meaning it is probably best not to enquire too closely, but which has undoubtedly led to a new style of programming. PLANNER is a theorem-proving language: it tries to establish the truth of assertions, not in the normal uniform, proof-theoretic, manner, but by accepting a range of "programmed hints" about how best to proceed at any point. In a language understanding program like Winograd's this means replacing familiar grammar rules such as:

 $S \rightarrow NP + VP$ 

(a sentence consists of a noun phrase followed by a verb phrase) by procedures, in this case:

((PDEFINE SENTENCE ((PARSE NP) NIL FAIL)((PARSE VP) FAIL FAIL RETURN)))

The details of the notation need not detain us; what is important is that Winograd's grammar is not the conventional list of rules, but small sub-programs like the line above, that actually represent procedures for imposing the desired grammatical structure. The definitions of more complex words are also in this form: here, for example, is the "theorem" defining the meaning of "pickup".

(DEFTHEOREM TC-PICKUP(THCONSE (X (WHY (EV))EV)

(#PICKUP \$?X)(MEMORY)(THGOAL(#GRASP \$?X) (THUSE TC-GRASP))

(THGOAL (#RAISEHAND)(THNODB)(THUSE TC-RAISEHAND))

(MEMOREND (#PICKUP \$?EV \$?X))))

Once again detailed explanation of the notation is not needed to make it clear that the word is being defined in terms of a number of more primitive sub-actions, such as RAISEHAND, each of which must be carried out in order that something may indeed be picked up. The linguistic content is a "systemic grammar"<sup>4</sup>; plus a simple system of semantic "features" marking words and arranged hierarchically, such as PHYSOB (for physical object words) and ANIMATE (for animate words like "robot"); together with some factual knowledge about the block world. Both types of knowledge, linguistic and factual, are represented in PLANNER and the program has access to whichever sort is required at any given moment, rather than proceeding in the conventional manner by first parsing to get a syntactic structure and then manipulating the features to get a semantic structure.

#### Significance and shortcomings of SHRDLU

One reason for the enormous impact of this work was that, before its appearance, AI work was linguistically trivial, while • the systems of the linguists had no place for the use of inference and real world knowledge. Thus a very limited union between the two techniques was able to breed considerable results. Before Winograd there were few programs in AI that could take a reasonably complex English sentence and ascribe any structure whatever to it. In early classics of "natural language understanding" in AI, such as Bobrow's STUDENT<sup>5</sup> problem solver for simple algebra, input sentences had to be short and of stereotyped form, such as "what is the sum of . . . ?" Conversely, in linguistics, there was, until very recently, little speculation on how we understand the reference of pronouns in such elementary sentences as "The soldiers fired at the women and I saw several fall," where it is clear both that the answer is definite, and that finding it requires some inferential manipulation of generalisations about the world. The reader should ask himself at this point how he knows the referent of the pronoun in that sentence.

So far, the reaction to Winograd's work has been wholly uncritical. What would critics find to attack if they were so minded? First, that his linguistic system is highly conservative, and that the distinction between "syntax" and "semantics" may not be necessary at all. Second, that his semantics is tied to the simple referential world of the blocks in a way that would make it inextensible to any general, real world, situation in which, for example, "block" might mean "an obstruction" and "a mental inhibition", as well as "a cubic object". The ambiguity of "in" in "He ran the mile in five minutes", and "He ran the mile in a paper bag", would also seem to be beyond its powers of resolution.

Third, the blocks world is strongly deductive and logically closed. If gravity were introduced into it, then anything that was pushed in a certain way would logically have to fall. But the common sense world, of ordinary language, is not like that: in the "women and soldiers" example given earlier, the pronoun "several" can be said to be resolved using some generalisation such as "things shot at and hurt tend to fall". There are no logical imperatives there, even though the meaning of the pronoun is perfectly definite. One might summarise these criticisms by paraphrasing a central argument of Wittgenstein's that the interesting point is not the creation of a language of the blocks world sort, but how different it is from our own.

Indeed, it might be argued that Winograd's system is not about natural language at all, but about how goals and subgoals are to be organised in a problem-solving system capable of manipulating simple physical objects. The definition of "pickup" quoted above is in fact an expression of a procedure for picking up an object in the SHRDLU system. Nothing about it would help one understand the perfectly ordinary sentence "I picked up my bags from the platform and ran for the train."

On the other hand, it has not been shown that the language

facilities just outlined cannot be incorporated in the linguistic structures that SHRDLU manipulates; and even if they could not, the work still would be significant by virtue of its original control structure and its demonstration that real world knowledge can be merged with linguistic knowledge in a working whole.

#### Paradigms and procedures

Winograd's work is a central example of the "artificial intelligence paradigm of language", using "paradigm" in Kuhn's sense of a large scale revision in scientific thinking, where the paradigm revised is the generative paradigm of the Chomskyan linguists8. From the AI point of view, the generative linguistic work of the last fifteen years has three principal defects. First, the generation of sentences, with whatever attached structures, is not in any interesting sense a demonstration of human understanding, nor is the separation of the wellformed from the ill-formed by such methods; for understanding requires, at the very least, both the generation of sentences as parts of coherent discourse, and some attempt to interpret, rather than merely reject, what seem to be ill-formed utterances. Second, Chomsky distinguishes between performance models, on the one hand, and competence models which are the province of serious linguistic study, on the other. Whatever his intention, this had had the effect of isolating modern generative linguistics from any possible test of the systems of rules it proposes, since testing necessarily involves performance. AI, though it too is concerned with the structure of linguistic processes per se, is equally interested in their implementation. Third, there was until recently no place in the generative paradigm for inferences from facts and inductive generalisations, even though very simple examples demonstrate the need for it.

These points would be generally conceded by those who believe there is an AI paradigm of language understanding, but there would be far less agreement over the positive content of the paradigm. The trouble begins with the definition of "understanding" as applied to a computer. At one extreme are those who say the word can only refer to the performance of a machine: to its ability say, to sustain some form of dialogue long enough and sensibly enough for a human interrogator to be unsure whether what he is conversing with is a machine or not. The majority, however, probably argue that this is not enough: the methods and representations of knowledge by which the performance is achieved must be of the right formal sort, and mere performance based on ad hoc methods does not demonstrate understanding.

This issue is closely related to that of the role of deduction in understanding natural language, simply because deduction is often what is meant by "right methods". The dispute over deductive methods on the one hand, and other inferential systems closer to common sense reasoning on the other, is in many ways a pseudo-issue because it is so difficult to define clearly what a non-deductive system is: almost any set of formal procedures can be expressed deductively. The heart of the matter concerns the most appropriate form of representation of knowledge, rather than how that knowledge could conceivably be expressed, and it may well turn out that the most appropriate form is nondeductive. The same insight has largely defused another heated issue; whether the appropriate representations should be procedures, as in Winograd's work, or declarations. One disadvantage of procedural representations is that if each item of "knowledge" is attached to a procedure for achieving a particular goal, it will have to be stored separately for each different goal for which it may be used; and if you want to change it later, it will have to be changed separately for each. Another is that conventional, declarative grammars are easier to understand; and Winograd's procedural grammar has been rewritten in more conventional form9 for that reason.

While there is now general agreement that any system should show how it is actually to be applied to language, it is no longer fashionable to demand that it must be written in a procedural language, like PLANNER.

#### "Second generation systems"

When Winograd contrasted his own with what he called second generation systems, he meant, as always in this subject, generations of fashion, not chronology or inheritance of ideas. The foundations and terminology of the approaches he discusses were set out in print in 1966, 1967 and 1968 (refs 10–12). In an already very influential recent paper (unpublished but available from the Artificial Intelligence Laboratory, MIT), Minsky has drawn together strands in the work of these authors and of Charniak<sup>13</sup> using a terminology of "frames":

"A frame is a data-structure for representing a stereotype situation, like a certain kind of living room, or going to a children's birthday party. Attached to each frame are several kinds of information. Some of this is information about how to use the frame. Some is about what one can expect to happen next. Some is about what to do if these expectations are not confirmed."

"We can think of a frame as a network of nodes and relations. The top levels of a frame are fixed and represent things that are always true about the supposed situation. The lower levels have many terminals—"slots" that must be filled by specific instances or data. Each terminal can specify conditions its assignments must meet . . . Simple conditions are specified by markers that might require a terminal assignment to be a person, an object of sufficient value etc . . ."

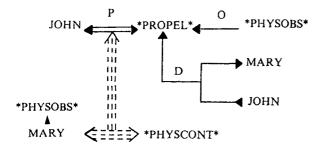

The key point about such structures is that they attempt to specify in advance what is going to be said, and how the world encountered is going to be structured.

In psychological and visual terms, frame approaches envisage an understander as at least as much a looker as a seer. The new work which owes most to Minsky's advocacy is Charniak's. He studied what sorts of inferential information would be needed to resolve pronoun ambiguities in children's stories, and in that sense to understand them. One of his example "stories" is: "Jack was invited to Jane's birthday party. She wondered if he would like a kite. A friend told Jane that Jack already had a kite, and that he would make her take it back".

The problem is to decide whether the penultimate word "it" refers to the first kite mentioned or the second. Charniak's system does not actually run as a program, but was a theoretical structure of rules called "demons" that correspond roughly to what Minsky later called frames. A demon for this example would be "If we see that a person might not like a present X, then look for X being returned to the store where it was bought".

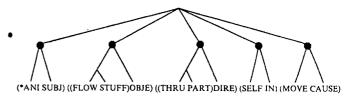

The other systems within the frames approach are rather different. Instead of resting on representations that are superficial in the sense, in which the demon above is just a sentence in English (or in some item-to-tem correspondence to one), they are based on reduction to a system of linguistic primitives, and it is at that level that the understander's computations must take place.

Schank's system takes English sentences and produces paraphrase style inferences from them. So, from "John strangled Mary", it produces "John caused Mary to die", "John placed his fingers about Mary's throat" and so on. His internal structures, that he calls conceptual dependencies, may be exemplified by the following for "John hit Mary".

The items between asterisks are primitive actions, a different types of arrow denote different types of relation

My own system, which I call preference semantics, runs an English-French machine translation system, which proa very clear test of the correctness of the inferences. example, from "The monkeys ate the bananas although were not ripe, because they were very hungry" it would tran the two "they's" correctly by different French pronouns beca of what it knows about hunger and ripeness. It does this looking for the most coherent representation in which conce find their "preferred connections" to others. In this ca "ripeness" prefers to be of plants though the system would n balk at "The old man was ripe with years" where that preferencannot be satisfied. It will also tackle examples like the "wome and soldiers" one, where it has to bring to bear rules of partia inference about the usual course of the world. These inference rules pattern-match and chain together complex structures of primitives called templates: networks whose nodes have tree structure like the following one for the action "drink":

#### (\*ANI SUBJ)((FLOW STUFF)OBJE)((THRU PART) DIRE)(SELF IN)(MOVE CAUSE)

This is to be interpreted, from the left, as drinking is a causing to be of a preferred liquid object (FLOW STUFF), by a preferred agent that is animate \*ANI, and of causing the liquid to be inside the animate thing (SELF IN), via an aperture (THRU PART). The important difference between this system and Schank's on the one hand, and Winograd's on the other, lies not in the semantic markers used, but in the ways they are related in advance in the semantic structures. So, for example, the understander could infer from the above tree structure for "drink", when incorporated in an appropriate template, that, after the act of drinking, the liquid (whatever it is) is inside the drinker. Such an inference would be essential to the resolution of the pronoun in a sentence like "John drank no gin in his cocktail but it felt warm in his stomach nonetheless".

#### Outstanding points of contention

There are many points of dispute between the proponents of second generation systems: such as whether one should make massive forward inferences as one goes through a text, keeping all one's expectations intact, as Charniak and Schank hold, or whether, as I hold, one should adopt some "laziness hypothesis" about understanding, and generate deeper inferences only when the system is unable to solve, say, a referential problem by more superficial methods.

But the most important argument concerns the question of level: whether the representation should be superficial and highly particular, or deeper and more general. Schank and I hold that the the core of understanding consists of very general, and sometimes almost vacuous, inferences about human behaviour, desires and expectations, manipulation of which requires a highly structured primitive representation, and not just the English-words-plus-variables approach of Charniak. This becomes very clear when one actually builds a system that takes English input and deals with it from scratch. Charniak and Minsky believe that this initial "parsing" can be effectively decoupled from the interesting inferential work and simply assumed. But that is not so, because the initial parsing actually depends on many of the later inferences, so the assumption of decoupling can lead to something like a circularity. For example, in analysing "He shot her with a colt", we cannot ascribe any

structure at all until we can make the inference that guns rather than horses are instruments for shooting.

Another distinction arises on the question of syntax analysis. Syntax, which is the heart of Winograd's system, is discounted by both sorts of frame approach, though for very different reasons. Charniak discards it because it is part of the initial parsing from which his inferential work has been "decoupled"; Schank and I do so because we believe semantic analysis to be fundamental, and that in an actual implementation the results of syntactic analysis can all be achieved by a sufficiently powerful semantic analyser. And this last assumption is confirmed by the limited degree of success that the two semantic analysers have actually achieved.

Closely connected with the dispute over the appropriate level of representation of knowledge is another as to what is the most pressing task in the immediate future. I would maintain strongly that work on understanding systems needs a well defined task somewhere between the trivial and the fantastic. If first generation systems sometimes seem trivial, then some of the goals of the more recent work seem fantastic, and at the present stage of our ignorance I would include in that category analysis of any prose, whether children's stories or whatever, that appears to contain problems for the average reader. I find I have to think. about the right analysis of Charniak's kitestory, discussed above. This is not true for most sentences, even though it is genuinely difficult to specify uniform rules for their analysis. I consider concentration on problem examples, to the exclusion of more natural language, to be a bad inheritance from AI's problemsolving past. On the other hand, not all understanding can be tackled by deep semantic representations: any machine understander that analysed the sense of "good morning" in order to find the correct reply would be making a fundamental error.

Again, a reasonably fluent speaker of, say, German, might well not understand a German conversation about birthday presents without detailed factual information about how Germans organise the giving of presents. Conversely, an expert might understand much of a technical article even with very little

knowledge of the language in which it was written. These considerations tell for Charniak's approach, and it is perhaps paradoxical that the sort of natural language understander that would tend to confirm his assumptions would be one concerned with discourse about, say, the details of repairing a motor car, where factual information is what is central, yet he has concentrated on something as general as children's stories, which need deeper assumptions about human desires and behaviour. That has sometimes seemed to move his research towards the fantastic, and has so far prevented its actual implementation.

In the end the differences about level of representation may again turn out to be ones of emphasis and of what is most appropriate to different subject areas. We should soon see whether that is the case, or whether one "frames approach" is right and the other wrong. It would be nice if this were to be settled by computation rather than by another change of fashion.

# Where is experimental research on earth strain?

P. H. Svdenham\*

Progress in experimental earth-strain research depends crucially on the measurement capability of its instruments, which are here subjected to critical review.

SERIOUS high sensitivity measurement of earth strain began forty years ago and many interesting experiments have since been proposed. A large number of research themes still await study, however, because of the lack of suitable instruments and installation experience. This article provides an overview of the experimental aspects, including rival mechanical and optical designs, in order to compare their shortcomings and provide us with guides for future research.

What is needed is a measurement capability like that provided by magnetometers or inertial seismometers which can measure a large number of parameters within hours of arrival at virtually any site.

#### Information to be desired

Depth of penetration of a radiation wave into the Earth increases with signal period. Gravitational potential is, therefore, valuable in investigations of the Earth's deep structure because it provides well isolated forcing frequencies ranging in period from hours to years. It is now virtually routine to extract the frequency spectrum from the original

\*Cooney Observatory, Department of Geophysics, University of New England, Armidale NSW 2351, Australia.

time domain strain record and numerical examination of this can yield data about the composition of the crust and mantle, and about earth resonances.

Complete specification of regional strain induced in rock requires knowledge of six strain components. If the directions of the principal axes of strain are known the monitoring task can be simplified because fewer components need measuring. At present, neither applied theory or instrument siting procedures are sufficiently advanced for making accurate assumptions about the axes. Indeed, recent reports, concerned with unexpected results obtained with tidal tiltmeters1,2 and strainmeters3, indicate that an instrument sees a regional component that can be much modified by the local structure and measurement cavity shape.

If experimental measurements lead us to generalised rules about the direction of the principal axes (criteria which hopefully need no measurements at each site) this should make it possible to investigate regional effects with less than six strainmeter components. Until more is known about this problem it hard to see how isolated strainmeters (singly, in colinear arrays or otherwise) can be used to study regional phenomena.

Theoretical studies will certainly help but multi-com-

ponent tensor arrays of strainmeters must be used to establish the components at each point: large area strain should not be extrapolated for data from a single strainmeter.

A closely related question is that of strainmeter length. No evidence so far presented proves which interval is optimum. Earlier reports favoured long intervals to average out varying rock properties, but comparative records4 now seem to show that length is less critical than was thought. If metre-length gauges could be used it would considerably ease site selection. The first reports of satisfactory short mechanical instruments are published in this volume4,5. Although the feasibility of surface installations<sup>6,7</sup> has been clearly demonstrated with laser-based instruments the sophistications used contrast sharply with a simple mechanical instrument installed in an underground chamber. It is doubtful if theory alone will be able to provide a close enough model of real local-rock situations for strains are induced by many varied processes. Tensor arrays of cheap instruments could well provide the sought-after generalisations for considerably less effort.

Allied questions are: does regional (fractured, inhomogeneous in practice) rock deform in a truly elastic manner? Are there significant mechanical hysteretic effects? How does fractured hard rock respond? King<sup>8</sup> has suggested that soft rock locations are preferable but this has not been verified in practice.

Few positive statements can be made about such problems: some answers are beginning to emerge. Mounting methods, for example, show that the technique used to couple the instrument to the rock is of little importance once an adequate settling time has passed. An instrument can now be installed within the hour to provide useable strain data within days, which represents a considerable improvement over methods of a decade ago.

Before regional effects can be confidently investigated experience must be gained in setting up an instrument consistently. As earth strains do not repeat with time it is of little value to reinstall an instrument to check validity. Instead the simultaneous comparison of two or more instruments on a common Earth interval or a special purpose test base must suffice. Until quite recently this powerful metrological procedure was totally ignored.

Reports of comparisons between instruments are rare. Is this because few attempts have been made or because few have been successful? The seven day runs of the first Invar-catenary instrument and a laser interferometer compared well<sup>10</sup> for most (but not all) of the period. Vali *et al.* published<sup>11</sup> the result of a 36-h run obtained with an interferometer and a quartz-tube instrument, but they contain major discrepancies. It is only in the last year that reasonable multiple recordings on a common rock interval have been reported<sup>4,16</sup>. In both instances the duration of records was long enough to provide confidence in routine use of strainmeters.

Dipping plates at continental boundaries should be subject to abnormal strains. Strainmeters for studying this would need to be very stable and reliable. Any measurement proposals for testing the theory of an expanding Earth<sup>13,14</sup> fall in this category.

The rate of dissipation of tidal energy has been calculated at about 10<sup>19</sup> erg s<sup>-1</sup>. As the resonance quality factor of the solid earth is several orders of magnitude larger than for the oceans, only a small percentage of this energy is dissipated in the solid-tide vibrations. Study of solid tidal signal phase variations might yield an appreciation of the magnitude and uniformity of the energy loss process. Indirect progress toward solid tidal measurements has been made<sup>15</sup> through a better understanding of the ocean loading effects that may mask the expected small phase delays.

There are many other problems. How deep do surface thermal strains really propagate? How important is the adiabatic heating (induced by ambient pressure changes) on the instrument and the measured rock interval? How local topography related to the directions of the prix strain axes? How far can the individual strainmeters tensor array be separated if a regionally represent tensor is to be obtained? .

#### Are strainmeters good enough yet?

To look at the current state of nanostrain measureme it is necessary to study the fundamentals of each designoring the sophistications that can veil the principl Strainmeters consist of a length standard that is comparagainst a rock interval using a micro-displacement detetion method. The standard used in geophysical strainmeter may be mechanical or optical.

The first mechanical nanostrain gauge used a steel pipe, 20 m long, as the standard with an electromechanical velocity detector. This work by Benioff, in 1935, provided the first tidal records to justify theoretical predictions of rock tide. By 1950 the relatively poor thermal coefficient material—steel—has been replaced by 50 mm diameter fused-silica tube. Many similar instruments have been commissioned since then<sup>18</sup>. The choice of transducer is a matter of personal preference for inductive, capacitance and optical alternatives can each provide the sub-nanometre resolution needed<sup>17</sup>.

In 1951 Sassa reported an alternative method using an Invar wire suspended between two pillars<sup>18</sup>. A mass hung in the centre moves ten times as much vertically as it does horizontally. There are, however, problems of gain variation with sag change. Today there is little need to incorporate mechanical amplification as electrical transducers are, able to provide adequate gain<sup>17</sup>. A still simpler wire method<sup>19</sup> consists of an Invar wire hanging in an horizontal catenary. A beam balance provides the necessary tension and monitoring facility. Rotation of the balance, as the rock interval varies, drives the transducer.

This method rapidly gained acceptance<sup>20,22</sup> and about seventy instruments are now in use as the cheapest and easiest strainmeter design available. The Cambridge group operate the majority of operational catenary instruments<sup>16</sup>, having installed them in many different global locations.

The chief difficulty in the original catenary design was the relatively large creep in length of the Invar<sup>21,23</sup> for this required frequent readjustment to maintain the record on-scale. Automatic chart ranging was constructed by two groups<sup>20,24</sup> to overcome this. (Drift from this cause reduces the precision of secular earth drift estimates and other long-period phenomena.) In many ways<sup>22</sup> Invar is not the best material for this purpose. An improved form of tensioned-standard meter has been developed with fused-silica canes linked together as a chain<sup>12,25</sup>. It was found to exhibit considerably less creep than Invar, improved dynamic performance and better tolerance to thermal contamination. It is important to note that no mechanical strainmeter has been provided with environmental control measures always used in laser instruments.

An interferometer can be used to detect small movements between a distant reflector and a beam splitter or reference reflector of Michelson and Fabry-Perot forms. Claims that this is the almost perfect strainmeter cannot be accepted. Whichever design is used three requirements must be met. First, the radiation must be stable in wavelength to the same order as the drift required (10<sup>-10</sup> h<sup>-1</sup> at least). This calls for the use of the new molecular absorption stabilised lasers. One of the four operational laser designs uses absorption in methane<sup>26,27</sup>, another in iodine<sup>28</sup>; one uses a mechanical etalon cavity<sup>6,7</sup>, a second iodine stabilised unit will be operational shortly<sup>28</sup>. On this factor alone it is hard to envisage cost reductions reaching a point comparable with mechanical designs. Reliability is also a parameter to be reckoned with at present.

The second necessity is to stabilise the radiation path

because ambient pressure, humidity and temperature variations alter the refractive index (and hence apparent strain) to a degree similar to the effects of environment on a fused-silica standard. An adequate environment is generally provided for optical meters by evacuating the optical path an expensive investment that is costly to maintain.

The third requirement is to use the interferometer principle for making a transverse comparison with the mechanical rock interval. This involves the use of mechanical components-mounts, optical elements and holders for same. As these are within the measurement loop they may introduce creep and environmental errors which are not easily quantified. One study of Fabry-Perot etalon stability indicated30 that the reflecting film changes were producing cavity length changes of 10<sup>-8</sup> per month.

Other claims must be carefully considered—that of wide bandwidth, for instance. Counters can respond to 10 MHz with ease but fringe-counting alone rarely provides adequate resolution (1 km interval just suffices). Opto-mechanico interpolation can divide the fringe to 1% but introduces bandwidth limiting mechanisms. The problem is overcome by using methods that provide a beat frequency output but, even so, the frequency stabilisation servos involve the use of bandwidth limiting mirror drivers. Further, the mechanical mounting elements possess natural resonances around 1 kHz so it is unrealistic to talk of extremely wide bandwidth. Furthermore, wide bandwidth is a hollow criteria for crustal movement research rarely needs better than one second response time.

With so few laser instruments running7,27,28 it is perhaps still too early for an assessment, but they seem to be inferior to mechanical devices. Several reports include statements about secular strain change: 10<sup>-10</sup> per day<sup>26</sup> and 10<sup>-9</sup> ground compression<sup>6</sup>. These statements are of limited value for observed drift rates cannot be attributed to ground or instrument as separate entities. (Similar overall drift performance has been achieved12 with fused-silica instruments.)

#### Ultimate stability—mechanical or optical?

A mechanical length standard is generally regarded as inferior to an optical one. Recent research, however, has shown that fused-silica can achieve a similar drift rate as the laser method showing that both need consideration in earth strain applications. Brownian movement of the internal molecules of a mechanical object provides a theoretical limit to its length stability. Relative size changes due to this would be around 10<sup>-15</sup> (one second averaging time) and experimentalists have reached this limit in small devices. It is yet to be shown that a relatively long mechanical bar can be made as stable. The relative wavelength instability of laser radiation can be ascertained from theoretical considerations; the limit is around 10-14 for a 1-s integration time. As with mechanical standards this has yet to be reached; practice is currently limited to  $10^{-12}$ instability.

It seems, therefore, that there is little to choose between the two for stability, experimental art being the deciding factor at present.

#### The ultimate strainmeter?

Mechanical instruments are cheap but prone to environmental effects. A moderate increase in cost could provide the controlled surround which all laser devices have. Experience gained25 with test-base temperature control suggests that microKelvin stability is achievable and that the cost and reliability would be comparable with the vacuum system of a laser strainmeter. Passive31, rather than active water circulation, control would further reduce the cost.

Another course of action could be to use ultra-low expansion materials for the standard (3 10-8 K-1 thermal expansion coefficient).

A third, already used, alternative is to monitor the

influencing parameters, correcting the data or physical standard accordingly. This method does not protect the standard from stress cycling—a condition that introduces mechanical hysteresis strain changes. Furthermore it is hard to ensure that the correct parameter is monitored.

These above approaches seem logical but, in fact, do not meet the basic needs of the measurement problem. The current unstated aim is to devise a zero temperaturecoefficient instrument placing it in existing underground apertures. On two counts this is incorrect procedure.

First, as the chamber must be relatively large it will modify the parameter sought. Second, long term thermal changes to the chamber will also alter the rock dimensions introducing contaminating components in the record. Ultimately it will become necessary to correct for this.

It seems more logical to opt for an instrument that is submerged in the rock in an insignificant size aperture and which has its overall temperature-coefficient matched to the host rock. It has recently been shown that 1 m fusedsilica and Invar strainmeters are feasible so these could be installed into deeply drilled core holes arranged as a shell-burst to provide six components at one place. As the length-standard would always be at the same temperature as the rock, the thermal noise should be reduced without recourse to control of its environment.

Only when it is firmly established what strainmeters measure and when we are able to place them to measure what we need will we be able to significantly advance our knowledge of the deeper Earth. Earth strain measurements are, at last, beginning to be meaningful now that the basic requirements of the problem have been recognised.

Lamont-Doherty Geological Observatory, Palisades, New York, USA

A deep borehole on São Miguel encountered temperatures exceeding 200° C at a depth of 550 m. Subaerial volcanics persist to a depth of 786 m below sea level and indicate an average subsidence of 0.1 cm yr<sup>-1</sup> for the island over the past 690,000 Myr.

DEEP drilling is essential to the understanding of the process of the formation of oceanic islands. The petrology and geochemistry¹ of island rocks differs significantly from those of deep ocean crustal rocks and the structure underlying islands as defined by geophysical data differs from that beneath deep ocean floors. The contrast suggests that special deep processes operate beneath oceanic islands. Most volcanic islands are confined to near spreading plate margins during their active period and their formation may be associated with the ocean floor spreading process²,³. Periodically, voluminous volcanic activity indicates exceptionally high rates of subcrustal convective heat transfer and mantle hot spots or plumes have been postulated as the sources of this activity¹.⁴.

In 1972 geoscientists from Dalhousie University and Lamont-Doherty Geological Observatory initiated a deep drilling programme into the oceanic crust with an 800 m hole into the island of Bermuda in the western Atlantic<sup>5,7</sup>. It yielded some 1,000 volcanic units approximately equally divided between thin altered tholeitic pillow lavas and lamprophyric intrusive sheets. Our second borehole in 1973 was located on the island of São Miguel, in the Azores, and an initial report is presented here of the 981 m penetration of a complex sequence of subaerial and submarine lavas, pyroclastics and volcanogenic sediments.

The Azores form a group of nine islands aligned in a NW-SE trending chain which transects the Mid-Atlantic Ridge (MAR) at 39° N (Fig. 1). The East Azores Fracture Zone and the MAR intersect at a triple junction<sup>8</sup> in the vicinity of the Azores and the region is marked with (i) a sharp change of trend of the MAR, (ii) the broadening of the ridge into an extensive platform<sup>8</sup> (Fig. 1) and (iii) an unusually high positive regional gravity anomaly<sup>10</sup>. The islands east of the MAR trend obliquely to the proposed plate margins and follow a pronounced bathymetric lineament (Fig. 1), the Terceira Rift<sup>8,11</sup> which extends through

parts of Graciosa, Terceira and São Miguel. Krause and Watkins<sup>8</sup> suggest that the Terceira Rift represents a secondary spreading centre trending towards Gibraltar which originated approximately 45 Myr ago.

São Miguel, the largest of the islands, lies near the eastern extremity of the chain 400 km from the MAR crest. Its surface geology is dominated by four large calderas, three of which have erupted during historic times12 and have produced an extensive blanket of trachytic pumice which covers much of the island<sup>13,14</sup>. Surface rocks range compositionally from alkali basalts to trachytes15,16 and are exceptionally potassic17. We selected a drill site on the gentle flanks of the volcano Agua de Pau which rises to a maximum height of 950 m above sea level and has a diameter at sea level of approximately 15 km. Its surface deposits consist of voluminous trachytic pumice and associated basaltic lavas intercalated with occasional trachytic extrusives. The last recorded eruption from the summit caldera in 1563 AD produced a cover of trachytic pumice and Walker and Croasdale<sup>18</sup> document four similar eruptive events during the past 4,600 years. Agua de Pau must therefore be considered to be currently dormant, as sporadic seismic activity beneath the caldera and a number of boiling hot springs on the flanks also indicate.

#### Stratigraphy and petrology of the core

Drilling began at 72 m above sea level, but only partial core recovery was possible in the first 148 m because of unconsolidated pyroclastic and mud flow deposits. Below this depth core recovery was virtually continuous to 981 m where drilling terminated following steam production. A synoptic core log is shown in Fig. 2.

Extrusive lavas constitute 72% of the drill core and occur in 140 separate flow units of 4.8 m average thickness and 2.5 m median thickness. Alkali basalts, hawaiites and mugearites predominate and only three trachyte flows (6% of total flow volume) were encountered. In the top 763 m of core a subaerial origin for the flows is suggested by (i) massive nature of flow centres, (ii) complete absence of pillow structures, (iii) intercalation of numerous pyroclastic units lacking any indications of aqueous reworking or stratification, (iv) development of some lateritic horizons, and (v) occurrence of thick vesicular and autobreceiated

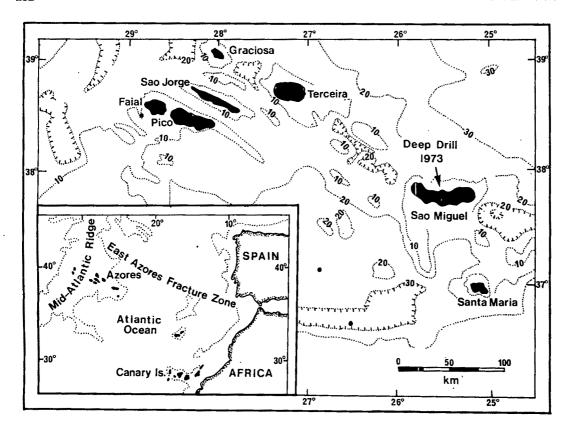

Fig. 1 Location map of Deep Drill 1973. Site coordinates 25° 31.4'W, 37° 48.9'N at 5 km from the caldera wall of Agua de Pau volcano, São Miguel. 1,000 m bathymetric contours are shown.

flow tops. Pillowed basaltic rocks with altered glassy margins were first encountered at 880 m where they are found interbedded with massive basaltic flows in a sequence devoid of pyroclastics.

In sharp contrast to the Bermuda drill core, intrusives constitute an insignificant fraction in São Miguel. Near vertical basaltic porphyry sheets in chilled contact with basaltic flows were encountered only at 662 m and 738 m.

Pyroclastic deposits, chiefly trachytic in character, account for 22% of the core and range from fine-grained tuffs to pumice deposits, agglomerates and mud flows. Indications of bedding are rare but when seen can be inclined steeply up to 30–40°. Steep depositional dips can also be seen in the recent ash-pumice deposits but these may not be an indication of tectonic tilting since contacts between flow units appeared to be near horizontal over the entire length of the core. Ignimbrite cooling units ranging in thickness from 6 cm to 3.8 m are common in the depth interval 262 m to 508 m. Only two such units have previously been described on the island<sup>17</sup>. Individual pyroclastic units are frequently trachytic in character at the base but grade upward into more basic compositions.

A 107 m thick igneous-sedimentary sequence marks the transition from subaerial to submarine volcanics. Basaltic breccias with a chloritic matrix (altered glass? or ash) are interbedded with massive flows in the upper part of the sequence (Fig. 3) and overlie 15 m of bedded coarse lithic sandstones. One 7 m bed consisting of angular basaltic fragments embedded in a matrix of black lithic sand (carbonate-quartz cemented) is strikingly similar to the black beach sands being formed along the Hawaiian coast line by flows entering the sea (Tilling, personal communication, 1974).

#### **Temperatures**

Bottom hole temperatures were monitored during drilling and temperature logs were measured at various intervals after drilling ceased (Fig. 4). The temperatures show 200° C water progressing upward from 550 m at the start to 290 m at the time of the last measurements. The boiling point was exceeded and steam erupted from the hole when the drill

rod was removed. The 200° C water would have boiled first when it reached the temperature-pressure boiling curve near 215 m depth. The steps in the last temperature profiles (for example at 110 m, 170 m, and 305 m) were produced by the convection water circulation in the hole because of loose ash sequences in which drill rods enlarged the hole considerably. Convection circulation in the hole is limited upward by tight basaltic and trachytic flows. It was also restricted above 305 m by casing.

Temperatures were nearly constant at 20° to 25° C to 100 m depth, a sudden jump to over 100° C occurred between 100 m and 175 m, then a uniform gradient of about 250° C km<sup>-1</sup> to a depth of 550 m and finally a very small temperature gradient of less than 10° C km<sup>-1</sup> to the bottom of the hole (Fig. 4).

In general, temperature profiles in hydrothermal areas show low vertical gradients in permeable rocks where the geothermal heat is carried upward by convection<sup>19</sup>. Impermeable rocks show high gradients since the heat must be carried through them by conduction. The region of this borehole is clearly not a normal hydrothermal system since the generally high porosity (and presumably high permeability) subaerial section above 550 m has a high gradient while the less permeable rocks below 550 m have a very low gradient. We suggest the following model to explain the observed temperatures.

The complete section penetrated by the hole probably does not permit vertical convection. Even though there are extensive permeable rocks (pyroclastics) above 550 m, circulation is restricted by frequent horizontal, impermeable horizons (flows). The lack of cellular convection is seen by the rapid change in measured temperatures with time when convection became possible in the borehole itself. Water flow parallel to the bedding (nearly horizontal), however, is probably not restricted in the permeable pyroclastic horizons. We suggest that there is hot water (205° C) flowing parallel to the bedding at about 550 m and water at 100° C flowing just under the impermeable layer at 110–120 m depth. The hot water probably moves down-dip in these horizons from its source in the upper regions of the volcano. There is no clear evidence for water flow in other

horizons. The low temperature gradient below 550 m suggests that there is no volcanic heat source directly beneath the drill site itself.

It is difficult to estimate the amount of hot water available in this area for geothermal power since no flow measurements were made. The hole erupted briefly with hot water and steam but was stopped after only 20 min, before any depletion of flow could be detected. The permeability of the core also has not been measured. Large volumes of 200°-210° C water may be available from near 550 m depth if the down-dip flow in the permeable horizons from higher on the volcano is rapid but flow tests are required to confirm this conclusion.

#### Age determinations

Palaeomagnetic measurements on lava flows in the core indicate that the subaerial, transition and subaqueous sequences are all normally magnetised. This probably indicates magnetisation during the Brunhes polarity epoch, although the possibility of remagnetisation during hydrothermal alteration cannot be discounted. If magnetisation does reflect geomagnetic field polarity the time scale of reversals of polarity of the Earth's magnetic field<sup>20</sup> provides an upper age limit of 0.69 Myr for the formation of the entire volcanic-sedimentary sequence.

Two samples were selected for radiometric dating by the conventional K-Ar method. The first of these, a slightly impure sanidine concentrated from a fresh trachytic flow located at 57 m depth has an apparent age of (117 $\pm$ 24)  $\times$ 10<sup>3</sup> yr (% K<sub>2</sub>O=6.7;  $^{40}$ Ar<sub>radiogenic</sub>/ $^{40}$ Ar=0.5). The second sample, a relatively fresh submarine lava from the 950 m level has an apparent whole rock age of (280 $\pm$ 140) $\times$ 10<sup>3</sup> yr (% K<sub>2</sub>O=2.7;  $^{40}$ Ar<sub>radiogenic</sub>/ $^{40}$ Ar=0.013). In other words, this

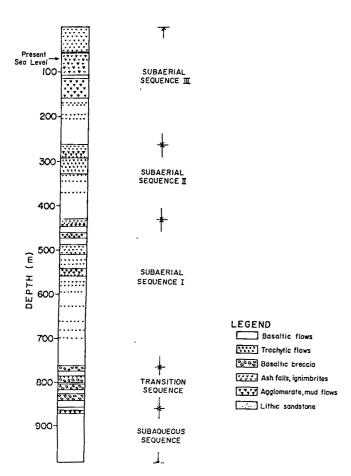

Fig. 2 Log showing major lithologic variations in the São Miguel drill core.

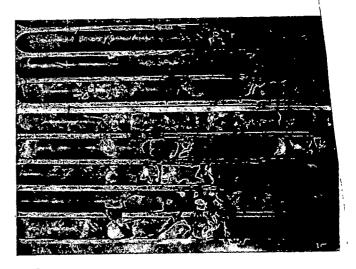

Fig. 3 Breccia from the transition zone consisting of angular basalt fragments of variable size in a matrix of coarse vulcanogenic sand and chloritic material. Basalt fragments show conspicuous leached margins. Length of core segments 0.6 m.

rock appears to have retained at least some radiogenic argon in spite of high ( $\sim 205^{\circ}$  C) temperatures encountered. The sample contained  $\sim 2.5 \times 10^{-6}$  s.c.c.  $g^{-1}$  atmospheric argon; an unusually high value perhaps indicative of exchange of gases between the lavas and overlying hydrothermal sources. We conclude from the radiometric and the magnetic data that the drill core spans a time interval of the order of a few hundred thousand years in the Brunhes normal polarity epoch and that the major vulcanism probably ended about 100,000 years ago.

Deep drilling on São Miguel has disclosed several important aspects of the island's geological evolution which are not evident from an examination of its surface geology. Three distinct subaerial eruptive sequences totalling 762 m in thickness were found to overlie a complex 107 m transition zone which documents the changeover from a subaerial to a submarine environment. Each subaerial eruptive sequence commenced with a quiescent phase of basaltic lava extrusion and was followed by increasingly explosive activity. Intercalated tuff beds increase in frequency and thickness and grade into a terminal phase of trachytic pumice deposition with rare trachyte extrusion. Compositional zonation within individual pyroclastic units further supports strong compositional zonation in the magma chamber at this stage. We suggest that each eruptive sequence signals the arrival of a fresh magma batch from depth in the mantle into a shallow magma chamber. Crystal fractionation and possibly assimilation at shallow depth would then yield increasingly differentiated products and an enrichment in volatiles; a combination which would in each case lead to increasingly explosive acidic eruptive activity.

#### Island subsidence

A surprising result of our experiment has been the depth at which submarine deposits were encountered. Subaerial or shallow marine conditions are found to 786 m below present sea level and indicate substantial subsidence of the island. Postglacial sea level rise since 18,000 BP can account for only 130 m of subsidence<sup>21</sup>. An evaluation of the glacial eustatic control of sea level for the earlier Pleistocene does not seem possible because of the largely unknown influence of tectonic crustal movements on sea level, but is not likely to be much greater. Paleomagnetic and radiometric dating of the core at younger than 0.69 Myr BP yields a minimum average subsidence rate of 0.1 cm yr<sup>-1</sup>. Other data on the vertical crustal motion in the

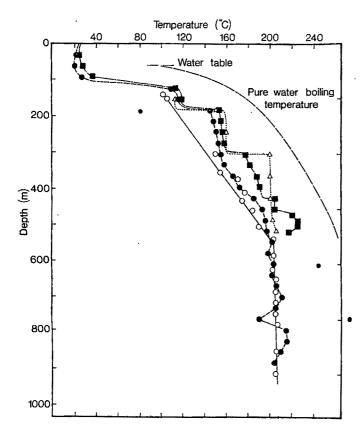

Fig. 4 Temperature measurements with maximum thermometers ( $\pm 2^{\circ}$  C) to 914 m during drilling; to 885 m with thermocouple ( $\pm 1^{\circ}$  C) between 1 and 2 h and again 4 days after termination of water circulation. Two days after further circulation maximum thermometer measurements were made to 518 m. O: temperatures at the bottom of the hole; temperature logs: ●: 26 August (1-3 h); ■: 2 September (4 d); △: 7 September (3 d).

Azores come from São Miguel's closest neighbour, Santa Maria, where a submarine sequence of basaltic volcanics and sediments of Miocene to Quaternary age is exposed22. This implies uplift for the island and suggests that the subsidence of Agua de Pau volcano is a local phenomenon.

The subsidence of ancient oceanic islands to form seamounts has been attributed to the thermal contraction of the lithosphere as it moves away from the spreading centre<sup>23-23</sup>, or to the vertical motion of the lithosphere as it slides over a bumpy asthenosphere<sup>26,27</sup>. In either case subsidence rates calculated from known spreading rates or theoretical models yield values of 0.01-0.02 cm yr<sup>-1</sup> which is an order of magnitude below those observed on São Miguel.

Detailed information on the vertical motion of other active volcanic islands is scarce. An analysis of tide-gauge measurements in the Hawaiian islands28 reveals recent subsidence rates of .0.5 cm yr<sup>-1</sup> for Hawaii, 0.2 cm yr<sup>-1</sup> for Maui, and stable conditions on Oahu. Decreasing subsidence rates correlate with an increase in the geological age of the islands and a decrease in intensity of their recent volcanic activity29. Ward30 has used raised shorelines and drilling data<sup>31</sup> from Oahu to demonstrate that Pliocene subsidence of the island was followed by uplift of 1.6 cm 1,000 yr<sup>-1</sup> during the Pleistocene.

São Miguel and adjacent Santa Maria exhibit a similar pattern. On Santa Maria, which is undergoing or has undergone emergence, neither historic eruptions nor any hot spring or fumarolic activity are reported. Volcanic activity has been dated to extend back 8.2 Myr<sup>32</sup>. The island is also furthest removed from active spreading centres such as the Terceira Rift. São Miguel, by contrast, shows rapid subsidence, active volcanicity, surface lavas dating from the historic era back to only 4.0 Myr<sup>12</sup>, and is situated on the currently active Terceira Rift.

The subsidence of an active volcano like São Miguel arises primarily from crustal loading with the addition of volcanic material. In Hawaii, Swanson<sup>33</sup> believes that simple isostatic adjustment adequately accounts for the observed subsidence. On a simple isostatic model the subsidence of 800 m observed on São Miguel requires the addition of a thickness of about 1 km of subaerial volcanic material to the island and will result in an increase of average elevation of 100-200 m. When a volcanic island becomes extinct, such as Santa Maria, erosion will result in isostatic rebound or uplift. If the top of the submarine section was 800 m below sea level when the island was active, at least 1,000 m has been eroded with a general reduction of elevation of 100-200 m.

Our temperature measurements suggest that the northern flank of Agua de Pau represents a promising prospect for future geothermal exploration. Bottom hole temperatures are well within the range of productive geothermal fields34 and occur at profitable depth. The thick subaerial volcanic sequence with its high proportion of pyroclastics and thick scoriaceous flow tops provides high porosities and possibly also permeabilities which make high flow rates probable. Further investigations to determine total hot water reserves, possible extraction rates, and the chemistry of the steam and water in this and other wells will be necessary for more specific evaluations. Seismic profiling to evaluate trap conditions near our borehole would seem a sensible next step.

# Observation of tissue metabolites using <sup>31</sup>P nuclear magnetic resonance

D. I. Hoult, S. J. W. Busby, D. G. Gadian, G. K. Radda, R. E. Richards & P. J. Seeley

Department of Biochemistry, University of Oxford, South Parks Road, Oxford, OX1 3OU, UK

<sup>31</sup>P NMR spectra of intact biological tissues can now be observed. The use of the spectra to study the course of reactions within the tissues is illustrated by experiments on muscle and its glycogen particle fraction.

Although phosphorus NMR has only 1/16 the sensitivity of proton NMR, it is attractive because studies may be done in aqueous solution and the spectra are relatively simple because of the small number of different chemical environments in which phosphorus atoms are found. In addition, the chemical shift range is much larger for phosphorus than for protons.

As a result of considerable instrumental improvements achieved recently in both the magnitude of the magnetic field and the sensitivity of the detection we are now in a position to study <sup>31</sup>P resonances in a large variety of systems at concentrations found naturally in biology, using Fourier transform and impulse response techniques2. Useful spectra can now be obtained of systems varying in complexity from solutions of purified enzymes to intact tissues.

#### Phosphate resonances

At the high magnetic field strength employed (7.5 tesla) the <sup>31</sup>P resonances of a large number of biologically important phosphate-containing compounds can be resolved. The chemical shifts of the phosphate groups are in the range of about 30 p.p.m., and many sugar phosphates and glycolytic intermediates can be resolved. Furthermore, the state of ionisation of the phosphates and their interaction with metal ions, such as Mg<sup>2+</sup>, affect the positions of the resonances. Figure 1 shows <sup>31</sup>P spectra of a mixture of compounds recorded at various pH values, the individual resonances having been assigned by observing the spectra of the individual components.

The resolution of the resonances from various phosphoruscontaining small molecules allows rapid assay of the components of mixtures of these molecules. Measurements are carried out without destruction or dilution of the sample, and provide a method of monitoring turnover and interconversions of these molecules in organelles.

In the glycogen particulate fraction isolated from rabbit muscle, covalent enzyme regulation has been exhaustively studied<sup>3,4</sup> and transient phosphorylation of phosphorylase b has been shown to be the principal trigger for glycogen breakdown. The enzymes concerned are also regulated by small ligands. Therefore, knowledge of concentrations of these regulators at any point in the transient covalent activation is important for full understanding of the control mechanism<sup>5</sup>. Figure 2 shows the turnover of the phosphorus containing

ligands during a typical transient activation, obtained from a series of <sup>31</sup>P NMR spectra, recorded on a single sample. The active form of phosphorylase immediately catalyses glycogen breakdown, leading to the production of glucose-1-phosphate and so (by phosphoglucomutase activity) to glucose-6-phosphate. The production of glucose-6-phosphate is concomitant with phosphate utilisation. During the phosphorylation of phosphorylase b, ATP is converted to ADP. Because of the presence of adenylate kinase, which catalyses the reaction 2ADP 

ATP + AMP, and of AMP-deaminase, which catalyses the reaction AMP-IMP+NH<sub>3</sub>, the ADP initially formed is depleted and IMP—not distinguishable from AMP by  $^{31}P$  NMR —is produced. The instability of the nucleotide levels indicates that the system is not a very good model for extrapolation to the in vivo situation.

The assay technique outlined above has also been used to estimate the separate activities in a crude extract of homogenised rabbit muscle by following the sequential production of glycolytic intermediates. The mass action ratios for some of the

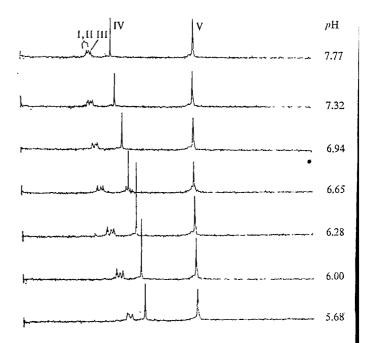

Fig. 1 <sup>31</sup>P NMR spectra of a mixture of fructose-1, 6-diphosphate (I, II), IMP (III), inorganic phosphate (IV), creatine phosphate (V) at various pH values, recorded at 129 MHz. No buffer present; total phosphate concentration 60 mM. Sweep width 5 kHz, pulse interval 2 s, 200 scans. Spectrum recorded without proton irradiation recorded without proton irradiation.

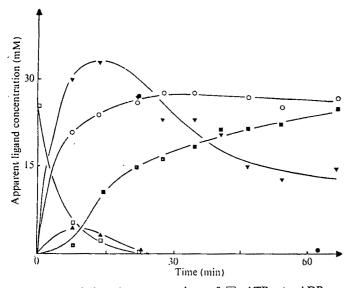

Fig. 2 Variations in concentrations of □, ATP; ▲, ADP; ○, AMP and IMP; ■, glucose-6-phosphate; and ▼, inorganic phosphate during flash activation of phosphorylase in glycogen particles. (27 mM ATP, 25 mM MgCl<sub>2</sub>, 1 mM CaCl<sub>2</sub>, 50 mM triethanolamine, 100 mM potassium chloride, 1 mM EDTA pH 6.9). ATP was added at time zero. Sweep width 5 kHz, Pulse interval 3 s, 50 scans. Spectrum recorded without proton irradiation. Differential saturation of the resonances can lead to small errors in the relative concentrations of ligands as measured from the areas under the peaks. The measured concentration of any ligand, however, is always a fixed proportion of its true concentration.

individual reactions have been deduced from the results obtained. The technique has also rapidly revealed the presence of contaminant activities in supposedly pure enzymes.

#### Metabolites in whole muscle

Our attempts to follow enzyme activities in intact tissues using phosphorus NMR have, to date, been principally concerned with observations on muscle from the hind leg of the rat. Figure 3 shows the <sup>31</sup>P spectrum of an intact, relaxed muscle, freshly excised from a rat killed by etheration. Assignments are made on the basis of the pH titrations mentioned in section 1. Part of the 'sugar phosphate' peak is attributed to

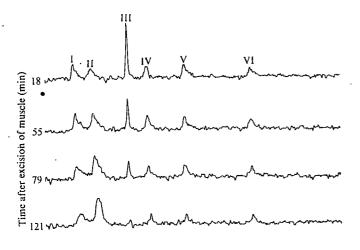

Fig. 3 <sup>31</sup>P NMR spectrum of an intact muscle from the hind leg of the rat recorded at 129 MHz, without proton irradiation. Temperature 20° C and pulse interval 16 s. Peak assignments: I, sugar phosphate and phospholid; II, inorganic phosphate; III, creatine phosphate; IV, γ ATP; V, α ATP; VI, β ATP. The times are the midpoints of the 50 scan spectral accumulations (referred to excision time as zero). The muscle was bathed in a minimum volume of calcium-free Locke ringer.

phospholipid as there is a broad peak of identical chemical shift in the phosphorus spectrum of debris from muscle extracted with aqueous buffer. Assays on this aqueous extract record a concentration of about 1 mM for glucose-6-phosphate. The frequency of the inorganic phosphate resonance defines the apparent pH of its environment (7.1 in this spectrum) and the frequencies of the ATP peaks correspond to those for the Mg<sup>2+</sup>-ATP complex at the phosphate pH. (The frequency of the creatine phosphate resonance is independent of pH around 7.) In vitro studies of Mg2+ binding to ATP show that there are large shifts (2-3 p.p.m.) in the  $\beta$ - and  $\gamma$ -phosphate resonances on complex formation. These shifts show that the ATP observed in muscle is almost entirely complexed to magnesium ion. Changes in ionic strength also produce measurable spectral shifts, but these are much too small to alter our assignments for the intact muscle spectrum.

The signal peaks of the muscle phosphates are broader than those for the corresponding compounds free in solution, and the inorganic phosphate peak is markedly broader than the ATP or creatine phosphate resonances. The explanation for this phosphate broadening cannot lie in a disturbance of magnetic field homogeneity caused by the nature of the sample as the width of the creatine phosphate signal gives an upper limit for

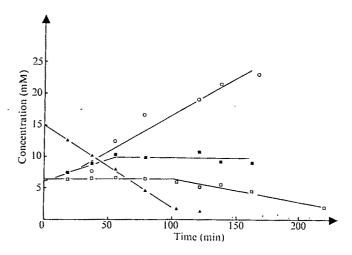

Fig. 4 Variation of phosphorus metabolite levels in an intact rat leg muscle with time after excision. The integrals of spectra shown in Fig. 3 are plotted in this graph. ○, Inorganic phosphate; ▲, creatine phosphate; ➡, sugar phosphate and phospholipid; □, ATP. An absolute concentration scale was established by running a standard sample of 10 mM phosphate in the same conditions as the muscle.

the field inhomogeneity. Inorganic phosphate has a pK at 6.9 whereas the nearest pK for creatine phosphate is at 4.6. The frequency of the former resonance is therefore strongly pH dependent around pH 7 whilst that of the latter is pH independent in this region. It seems likely that the large width of the phosphate line may be due to a distribution of pH within the muscle, that is to some partial compartmentation of inorganic phosphate. The pH range that would account for the linewidth is about 0.5 pH units.

We have measured the approximate concentrations ( $\pm 10\%$ ) of phosphorus metabolites in the intact muscle by integration of the absorption spectrum, using a sample of known concentration as a standard after taking care to avoid saturation of the resonances. There is some variation from muscle to muscle, and the creatine phosphate: phosphate ratio proves to be a sensitive index of the degree of stimulation of the rat muscle before the animal's death, that is a high creatine phosphate: phosphate ratio in rats killed without excessive stimulation. We have measured the concentrations of 'sugar phosphate', inorganic phosphate, creatine phosphate and ATP at intervals between 16 and 170 min from excision of the muscle (Fig. 4). Extrapolation along the time axis shows the metabolite levels

at the time the muscle was excised to be: sugar phosphate+ phospholipid, 6 mM; inorganic phosphate, 6 mM; creatine phosphate, 15 mM; and ATP, 6.5 mM.

Creatine kinase maintains the ATP level constant at the expense of creatine phosphate until all the latter substrate has been used up, demonstrating the ability of the kinase to buffer the muscle ATP concentration. Ageing of the muscle is accompanied by a fall in pH which is monitored by changes in the frequencies of the phosphate and ATP resonances. The pH at the start of data accumulation is 7.1, and after 160 min it has fallen to 6.2. Acid accumulation seems to accelerate at the time when the creatine phosphate concentration falls to zero and glycolysis presumably begins.

These results can only be obtained with intact muscle. Samples which are even slightly lacerated during handling have only an inorganic phosphate peak in the phosphorus spectrum. Breakdown of organic phosphates by phosphatases is assumed to have occurred in the damaged muscle.

#### Scope

On the basis of these experiments and other data we have obtained from a variety of biological systems, we believe that <sup>31</sup>P NMR can yield general information about metabolite levels, turnover, interactions and compartmentation. As it is

also possible to distinguish between signals from extrace and intercellular materials, in favourable cases the stud certain transport processes is now also possible. The delines of unusual pathways, the detection of possible new in mediates and the presence of bound nucleotides also se within the scope of the method. To what extent the kind structural information that is beginning to emerge from solution studies can be extended to the study of intercellu components remains to be determined.

This work is supported by grants from the Science Research Council (Oxford Enzyme Group) and from the Medic Research Council. The spectrometer was built in Oxford with grant from the Paul Instrument Fund of the Royal Society.

### Degeneracy effects on neutrino mass ejection in supernovae

THAT type II supernovae apparently occur predominantly in stars significantly more massive than the Sun has been known1 for some time, although a precise stellar mass range for these cataclysmic events can not be defined observationally. Recent theoretical interpretations<sup>2-4</sup> of diverse observational data seem, however, to indicate independently that the masses are significantly in excess of  $8M_{\odot}$ . Furthermore, observational evidence may exist that stars with masses below  $6M_{\odot}$  cease nuclear burning before a critical supernova configuration evolves. If this is the case, the total supernovae contribution from the stars of lower mass is negligible and theoretical difficulties6 associated with such events are resolved. The circumstantial evidence for massive  $(>8M_{\odot})$  supernova progenitors is thus reinforced, although problems arise in understanding the supernova mechanism.

Attempts to explain supernovae in massive stars theoretically have centred on either nuclear fuel detonation? or neutrino energy deposition<sup>8</sup> in the infalling envelope during dynamic stellar collapse. The former mechanism does not release sufficient energy (ref. 8 and Z. K. Barkat, J. C. Wheeler, J. R. Buchler and G. Rakavy, unpublished) to account for the type II explosion. The published results9 on the latter are in dispute10.11 but tend to be negative with respect to the required mass ejection. Recently it was suggested12 that the neutrinomatter coupling may be enhanced considerably through coherent scattering from nuclei. Subsequent hydrodynamic computations<sup>13</sup> required a fivefold increase in the theoretically estimated cross section for effective neutrino mass ejection. As coherent effects diminish at the high average escaping neutrino energy<sup>8</sup> (~50 MeV), the results are not very encouraging. Thus the posited mechanisms for massive stellar explosions seem inadequate.

The strong circumstantial evidence for massive supernovae progenitors, however, requires a critical re-evaluation. The comments in this communication will focus on the neutrino transport mechanism. All extant computations impose the condition of a zero chemical potential on the neutrinos. Arbitrary variations in the neutrino numbers result as a photon-like blackbody spectrum is maintained. Neutrinos and antineutrinos contribute to the total lepton number, however, and therefore can not be created or destroyed arbitrarily. Indeed I shall argue that the arbitrary zero chemical potential condition suppresses leptonic neutrino transport characteristics that may lead to supernova mass ejection.

My study was limited to high densities (>  $10^{11} \, \text{g} \, \text{cm}^{-3}$ ) where the diffusion approximation to neutrino transport obtains11. In this approximation the Boltzmann transport equation transforms by way of the Lorentz-Enskog method into a relationship between the nonisotropic neutrino intensity and the gradients in temperature and chemical potential. Appropriate integration over the neutrino spectrum (the canonical electron scattering opacity14 was assumed) then yields the Rosseland mean approximations for two neutrino fluxes, one for energy and one for particle number15.

Comparison of the resulting coupled energy/particle diffusion equations with that of the usual diffusion approximation16 indicates that the latter suppresses two potentially significant leptonic effects: energy transport caused by chemical potential gradients, and variations in the efficiency of thermal transport with particle number concentration (that is, chemical potential variations). As they have not been accounted for in the extant computations, the question arises of their significance for neutrino supernovae.

虚心

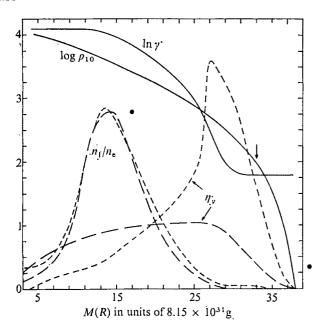

Fig. 1 The distribution of diffusion parameters with the total mass interior to a given radial point in the collapsing structure after diffusion has progressed for 0.445 ms. The parameters shown include the temperature  $(kT = \gamma m_e c^2)$ , the density  $(\rho = 10^{10} \rho_{10})$ , the ratio of the chemical potential to  $kT(\eta_{\nu})$ , and the ratio of the neutrino lepton number to that of equilibrium matter electrons. The arrow indicates where the gravitational free-fall time scale equals the elapsed time. — decoupled.

For a quantitative answer, the degree of neutrino particle/antiparticle interaction must be determined. Rapid interaction on transport time scales gives neutrino/photon equilibrium and will be referred to as the coupled transport mode. When no interaction is possible the decoupled mode obtains. Coupling may be mediated either through particle/antiparticle annihilation or through equilibrium in both urca reactions:

$$v_{e}[(Z, A), (Z+1, A)] e^{-1}$$
 and  $\overline{v}_{e}[(Z+1, A), (Z, A)]e^{+1}$ .

Electron pair production should dominate in neutrino annihilation as one and two photon processes cannot contribute17. Hence coupling will decrease with electron degeneracy. For thermalised neutrinos, coupling may be impossible on energetic grounds alone in electron-degenerate outer regions of collapsing supernova configurations, and a transition from coupled to decoupled transport may be possible between the hot central condensation and the collapsing outer envelope. The details of such a transition were ignored in this preliminary study, and only the extremes of total coupling and decoupling were investigated.

Neutrino diffusion was studied in a supernova ambience to determine the leptonic effects in transport. Coherent scattering by nuclei was neglected; thus muon neutrinos escaped essentially without interacting. The investigation used a stationary collapsed stellar density structure that corresponds to published results9 of hydrodynamic collapse at a given instant. The initial temperature structure was essentially that of Fig. 1 and the chemical potential was initially set to zero throughout. The shock energy and lepton number deposition was approximated by means of source terms using published shock structure estimates11. Ninety per cent of this energy was assumed to escape in the form of muon neutrinos<sup>9</sup>. The electron neutrino lepton number increased at the rate of matter transport through the shock to higher density with lower electron number<sup>18</sup>. The two equations for diffusion of energy and of particles were solved numerically for the coupled and decoupled transport modes. Fluxes were allowed to escape without interaction for densities below 1011 g cm -3.

The resulting configuration after 0.445 ms of evolution is shown in Fig. 1. A striking result for both transport modes is the concentration of neutrino lepton number at the shock front (its value was initially zero). The arrow indicates the point at which the hydrodynamic free-fall time equals the elapsed time of diffusion. The hydrodynamic time scale rapidly diminishes at the higher densities at which the neutrino lepton number concentrations occur. The neutrinos are therefore virtually trapped on hydrodynamic time scales and will fall with the matter. The rate of neutrino lepton number generation at the shock front is therefore greater than that assumed in the present static investigation. The actual hydrodynamic collapse of the matter will aggravate the chemical potential build-ups obtained.

The distributions of chemical potential for both diffusion modes is significantly different from zero. Pair energy transport inhibits the potential's growth in the coupled case. The large build-up for the decoupled case may indicate steep chemical potential gradients opposite to those of temperature if a transition from coupling to decoupling occurs.

The modifications on the hydrodynamics of supernovae that may be implied by these results are difficult to predict. An order of magnitude estimate of the energetic differences that could arise was obtained by continuing the above computations to 7.5 ms. For purposes of comparison with extant supernova computations a similar diffusion study was carried out for coupled transport subject to a fixed zero chemical potential condition. The net energy and lepton number escape from th. structure for the three different cases were as shown in Table 1.

Table 1 Net energy and lepton number escape						
Energy (erg)	Lepton number					
$8.6 \times 10^{51}$	$(N_{\text{Avg}}\text{-g})$ 2.7×10 <sup>32</sup>					
$2.7 \times 10^{51}$	$3.3 \times 10^{32}$					
$3.2 \times 10^{51}$						
	Energy (erg) 8.6×10 <sup>51</sup> 2.7×10 <sup>51</sup>					

The case in which a zero chemical potential is imposed most closely resembles the decoupled mode as far as energy is concerned. If a transition from coupled to decoupled diffusion occurs in actual supernovae, energy may accumulate at the transition point because of differences in diffusion rate. The above energy difference of  $\sim 5 \times 10^{51}$  erg is more than sufficient to give a type II supernovae. The possibility of such an accumulation of energy in the outer regions needs to be carefully considered.

These preliminary results indicate that the effects of lepton conservation may be significant in supernova neutrino transport. The validity of the diffusion approximation becomes questionable at lower temperature and density because of the long mean free paths of low energy neutrinos. The portion of the equilibrium neutrino spectrum thus affected is, however, relatively small over most of the collapsing supernova structure. Thus the general features of leptonic transport should be reflected in the results presented. The large magnitude of leptonic effects in diffusion shows that they cannot be ignored a priori. An extension of the multi-energy group transport approximation9 to allow for these effects is desirable.

I thank Professors A. G. W. Cameron and J. C. Wheeler for suggestions and Professor D. N. Schramm and Dr R. Epstein for criticism. This research was supported by the National Aeronautics and Space Administration. A more detailed report has been submitted for publication elsewhere.

### Measurement of atomic oxygen in the lower ionosphere using a rocket-borne resonance lamp

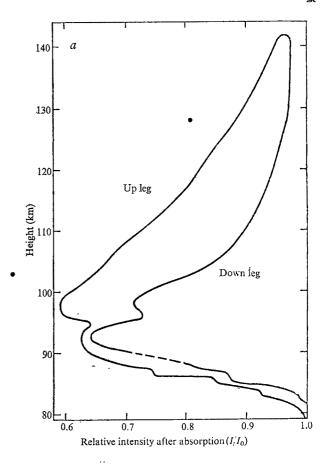

Atomic oxygen is an important constituent of the mesosphere and lower thermosphere because of its role in the excitation of the O I( $^{1}S_{0}^{-1}D_{2}$ )· airglow emission at 557.7 nm (ref. 1) and because of its involvement in the positive and negative ion chemistry of the lower ionosphere<sup>2</sup>. In particular it destroys negative ions<sup>3</sup> and can break reaction chains believed to produce water cluster ions below about 85 km (ref. 4). There is also uncertainty about the degree of dissociation of oxygen in the thermosphere<sup>5,6</sup> and atomic oxygen is involved in many reactions with neutral hydrogen/oxygen compounds in the mesosphere<sup>7</sup>.

Various experimental techniques have been used to measure the concentration of atomic oxygen [O] (refs 8-12) but most of these have serious limitations or uncertainties. We report direct measurements of night-time concentrations of atomic oxygen in the ground state, O ( $^{3}$ P), in the mesosphere and lower thermosphere by a new technique. Values of [O] from  $3 \times 10^{7}$  to  $5 \times 10^{11}$  cm<sup>-3</sup> have been found at heights between 79 and 142 km. The experiments were rocket-borne, and used resonance fluorescence and absorption techniques at the O I( $^{3}$ P- $^{3}$ S<sub>1</sub>) triplet, 130.20, 130.47 and 130.58 nm.

O I radiation was produced in the rocket payload by a resonance lamp of novel design. It consisted of a sealed coaxial radiofrequency discharge tube within which molecular oxygen was produced by a temperature controlled chemical source, balanced by a getter. The oxygen pressure was adjusted to give minimal self absorption of the 130 nm radiation by atomic oxygen in the discharge. This was determined by laboratory measurements of the relative intensities of the components of the triplet, which dominated the spectral output of the lamp at 10<sup>13</sup> photons s<sup>-1</sup> sr<sup>-1</sup>. The lamp also radiated at H Lyman-α (121.6 nm), at the O I (<sup>5</sup>S- <sup>3</sup>P) 136 nm lines, and at longer wavelengths.

The emission from the lamp was concentrated by a concave cylindrical mirror into a flat beam in the plane perpendicular to the rocket axis. A small part of the beam was reflected back by a corner reflector deployed on a boom and was detected by an ion chamber to measure absorption by ambient atomic oxygen over a 40 cm path. The ion chamber has a  $\text{CaF}_2$  window and NO gas filling and was operated at a gas gain of about 600. Radiation at 130 nm was the only emission from the lamp within the bandpass of the detector (123 to 134 nm).

A photomultiplier was used to count photons re-emitted by the ambient oxygen atoms due to resonance fluorescence under

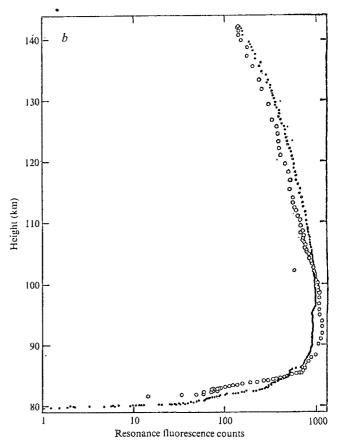

Fig. 1 a, Absorption of O I (130 nm) radiation over a path length of 40 cm through ambient atomic oxygen as a function of height for the complete rocket flight. b, Simultaneous measurements of the intensity of resonance fluorescence emission at  $\lambda = 130$  nm from ambient atomic oxygen as a function of height.  $\bullet$ , Up leg;  $\bigcirc$ , down leg.

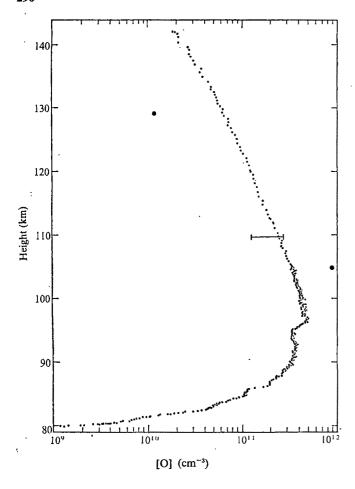

Fig. 2 Atomic oxygen concentrations calculated from the absorption and resonance fluorescence results as a function of height (up-leg data only). The error bar indicates the maximum range of uncertainty in the absolute scale.

irradiation by the ultraviolet beam. The lamp intensity was square wave modulated at 240 Hz so that phase-sensitive detection could be used to reject background signals due to airglow. A CaF<sub>2</sub> window was again used to suppress Lyman-a background. The field of view of the photomultiplier excluded all payload components.

The concentration of atomic oxygen which was required to produce a given degree of absorption was determined in the laboratory by measuring across a flowing afterglow in which known atomic oxygen concentrations were produced. This allowed absolute values of [O] in the ionosphere to be found from the absorption experiment in flight.

The resonance fluorescence experiment was not used to obtain independent absolute measurements of [O] because knowledge of all factors affecting the optical efficiency of the experiment would have been required, resulting in a relatively large uncertainty. But absolute values obtained from the absorption experiment are independent of these factors and were used to calibrate the resonance fluorescence for [O] values in the approximate range  $2 \times 10^{10}$  to  $5 \times 10^{11}$  cm<sup>-3</sup>. This calibration indicated some non-linearity in the resonance fluorescence count response at high count rates which was consistent with the known characteristics of the electronics as measured in the laboratory. At lower count rates a linear dependence of count rate on [O] was obtained and used to extrapolate the calibrations to [O] values below the range of sensitivity of the absorption experiment.

Two payloads, each including the above experiments and a Langmuir probe, and longitudinal and transverse magnetometers, have been flown on Petrel rockets. Rocket number P174H was launched at night and P173H at dawn. Each flight was followed within 20 min by a second Petrel rocket carrying a support payload to measure atomic oxygen using resistive silver film sensors<sup>5</sup> and electron density by Faraday rotation and Langmuir probe. Useful results were obtained from all four flights.

This letter deals solely with atomic oxygen concentrations from P174H. The flight was made from South Uist, Scotland (57° 20'N, 7° 20'W) at 2237 UT on April 1, 1974, under magnetically quiet conditions. It reached an apogee of 142 km and was spin stabilised. The experiments were all operating from 64 km upwards. The trajectory was determined from Döppler slant range measurements and radar tracking, and is accurate to better than  $\pm$  0.5 km in height.

The dependence of the measured absorption on height is shown in Fig. 1a. This may be compared with the counts from the resonance fluorescence in Fig. 1b, each point being the average of six counts sampled at 240 Hz. The derived atomic oxygen concentrations are shown in Fig. 2 for the up-leg data only.

In calculating the effective length of the absorption path in flight, molecular flow and complete recombination of oxygen atoms at surfaces have been assumed. If the surface recombination were low a stagnation zone of high [O] in part of the absorption path might cause an overestimation of the ambient concentration. In Fig. 2 this unlikely case is represented by the minimum density end of the error bar which indicates the range of uncertainty in the absolute [O] scale.

The atomic oxygen concentration was below  $3 \times 10^7$  cm<sup>-3</sup>, the lowest detectable value, until 79.6 km was reached. Incre an extremely rapid monotonic rise by a factor of 40 in 0.4 km occurred, which has been omitted from Fig. 2 to avoid undue contraction of the [O] axis. (The omitted data can be seen in Fig. 1b below about 10 counts.)

Between 80 and 97 km, [O] increased and the measurements showed departures from a smooth variation. These occurred between 82.5 and 83.5 km, between 84.8 and 87 km and between 93 and 96 km. These perturbations were detected by both the absorption and resonance fluorescence experiments on the up and down legs of the flight at the same heights. They are, therefore, considered to indicate fine structure in the variation of [O] with height and not an instrumental effect.

Above the maximum [O] at 97 km the fall off became approximately exponential with a scale height of  $14.9 \pm 0.6$  km.

On the down leg the resonance fluorescence response was lower and the absorption considerably lower than on the up leg, except at the down-leg maximum near 93 km where both responses were similar to the up leg. A reduced response was expected on the down-leg because of wake effects.

The rocket velocity was high enough to cause serious loss of resonance due to the Döppler effect if there were a significant component of the velocity along the ultraviolet beam. The beam geometry had therefore been chosen to make this error negligible on the up leg. But on the down leg, roll modulation was observed which may be attributed to the Döppler effect as predicted.

The concentrations shown in Fig. 2 are derived from up leg data only, for which attitude corrections are expected to be small except near apogee.

The results have been produced by analysis of ultraviolet paper records of the analogue data. We intend to publish fuller details of the experiment and more precise results from computer analysis of digital records later.

This work was part of a joint programme of D-region research by the Appleton Laboratory of the Science Research Council, and the University College of Wales, Aberystwyth; we thank Professors W. J. G. Beynon and N. D. Twiddy, Drs W. C. Bain and L. Thomas, and Mr E. R. Williams for advice. The rocket payload was instrumented by K. Slater and G. E. A. G. Barnett (Appleton Laboratory). The resonance lamp was designed at York University, Toronto, Canada, and developed and constructed by Intra-Space International Inc., Downsview, Canada. The lamp was calibrated at the UCW

which also provided the support payloads. Assistance with analysis of flight data was provided by Md Iqhbal Ahmed, Commonwealth Academic Staff Fellow, Andhra University, Waltair, India.

# Thermospheric winds from laser tracking of sodium clouds

NEUTRAL wind measurements in the thermosphere have been made on many occasions using ground based photographic¹ or photometric observations² of artificial clouds released from rockets. These clouds are visible either through a chemiluminous reaction, such as with trimethyl aluminium (TMA) releases, enabling night-time observations to be made at altitudes between 80 and 150 km or through resonance emissions of sodium, lithium, barium or aluminium oxide when clouds are illuminiated by sunlight, enabling twilight or daytime observations to be made above about 80 km.

To measure night-time winds at all heights above 80 km, in particular above 150 km, the normal limit of a TMA trail, we

have built a new mobile laser radar system which is used to track sodium clouds released from rockets. This letter reports the operation of the system during the United Kingdom high latitude rocket campaign at Andenes, Norway, in October and November 1973 and gives the wind profile obtained during one of the four successful flights.

The steerable laser radar (Fig. 1) was developed at the Appleton Laboratory from a fixed system previously used for studying the natural sodium layer by means of resonance scattering of a tuned laser beam<sup>3</sup>. The plane mirror, which is used to scan the laser beam around the sky, rotates about two axes, allowing the system to cover nearly half the sky. The scan is controlled

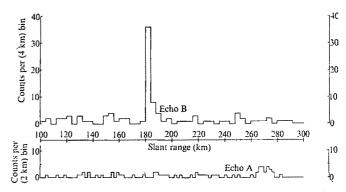

Fig. 2 Echoes from the sodium trail. Echo A (pulse No. 1007) is at 174.5 km altitude, 288 s after launch. Echo B (pulse No. 2885) is at 141 km altitude, 667 s after launch. The probability that the dark current and background signals, which should obey Poisson statistics, could produce a noise signal equivalent to these echoes is very small.

remotely in either manual or automatic modes. In the latter, a selected portion of the sky can be scanned in a raster. After each laser pulse, the photons detected by the photomultiplier are counted as a function of time delay and therefore slant range. The counts from each of 100 successive slant range intervals (where the intervals can be chosen to correspond to 0.5, 1, 2, 4 or 8 km), a time code and the angular coordinates of the scanning mirror are recorded in a suitable format on a digital cassette recorder for subsequent computer analysis. In addition analogue signals are reconstituted from the digital data to provide a quick-look record on an ultraviolet oscillograph for immediate analysis and also a real time display on a cathode ray tube of intensity of echo as a function of slant range for each laser pulse. The location of the detected cloud within a given raster is stored and displayed continuously on a second cathode ray tube. This real time information on position, intensity and slant range of the cloud echoes enables the operator to optimise the raster location and the slant range settings of the recording system for subsequent rasters.

The system was deployed at Skibotn (69° 22'N, 20° 18'E) about 170 km from the rocket range at Andenes (69° 18'N,

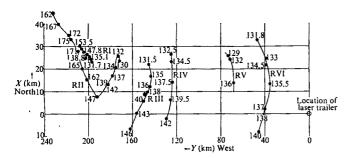

Fig. 3 Ground projection of sodium trial. I to VI, Raster number; altitudes (km) are marked. The coordinates and altitudes shown are means, derived from analysing between 20 echoes (Raster I) and 160 echoes (Raster IV) per raster.

16° 02′E). Sodium thermite burners which would release a sodium cloud in the form of a trail were launched on four Petrel rockets (P100A, P101A, P145A, P146A) and as part of the payload of one Skylark rocket (SL1123). Rockets P100A (October 14, 1973) and P101A (October 17, 1973) were used to provide initial tests of the system for developing operational techniques. SL1123, followed by P145A and P146A were launched on the night of November 16/17, 1973 at intervals of approximately 1 h during a strong auroral substorm. Four of the five sodium trail releases were acquired and tracked, the one failure (P101A) being because of a partial rocket malfunction which caused a very low apogee.

The data presented here were obtained from P146A which was launched at 0101:02 ut on November 17, 1973, into the recovery phase of an auroral substorm. The sodium trail started near 130 km on the up leg, continued over apogee (175 km) and rather weak outgassing of sodium vapour continued to about 160 km on descent (the apogee and descent portions of the trail appeared from the laser echoes to be optically thin). The laser radar was operated for 35 min after the trail was released with the system parameters given in Table 1. 1,500 echoes from the trail were recorded from 10,000 laser pulses. Figure 2 shows two echoes. From the intensity of echo B at an altitude of 141 km it was deduced that the trail was probably optically thick. The return from 174.5 km (echo A) is from a well diffused and optically thin region near apogee.

Figure 3 shows the projection of the sodium cloud on to the Earth's surface (geocentric coordinates) as observed with the first six rasters. An average wind profile, Fig. 4, was deduced by following the projected ground track of various altitudes between the rasters.

Strong eastward and southward wind components above 130 km seen during the experiment are probably consistent with those to be expected from a combination of ion drag accelera-

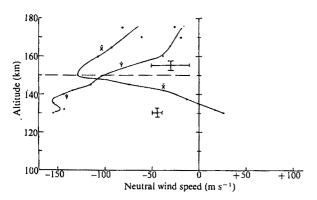

Fig. 4 Average wind profile for P146A.  $\dot{X}$ ,  $\dot{Y}$ , Northward and westward components of velocity. Error bars indicate the maximum errors ( $\pm$  3 standard deviations) in the two regions above and below -150 km.

tion and extensive heating in the auroral thermosphere during the auroral substorm of magnitude— $500\gamma$  (nT) at Andenes, earlier in the night. The significance of these results regarding thermospheric morphology during auroral substorms will be studied using the results of all three rockets (SL1123, P145A, (146A) launched during the substorm.

During this campaign the greatest altitude at which echoes and wind data were obtained was the apogee of the Skylark (215 km). From the intensity and duration of the signal received at 215 km, we estimate that the laser radar system we used for these experiments can obtain wind profiles from sodium clouds at over 300 km altitude, the predicted design limit. This technique gives a considerable extension of the upper altitude limits at which night-time wind measurements can be made from rocket releases.

We thank the staff of the Auroral Observatory, Trömso, for assistance in installing and maintaining the laser radar trailer at Skibotn. This was a collaborative project between University College, London, and the Appleton Laboratory of the Science Research Council. The rocket launches and the development work were supported by the Science Research Council. Mr E. Hammond helped to construct and operate the laser radar.

# Atmospheric halocarbons and stratospheric ozone

ODD chlorine<sup>1</sup> is a more potent catalyst for the destruction of ozone than is odd nitrogen<sup>2</sup>. Molina and Rowland<sup>3</sup> warn that chlorine released during the photochemical destruction of fluorocarbons (FCCs) constitutes a potentially serious threat to the integrity of the stratospheric ozone layer.

In the original investigations of the atmospheric distribution of FCCs (refs 4-7) these compounds were sought because of their unique usefulness as easily detected and unequivocal anthropogenic markers. Their presence in an air mass at elevated levels indicated its recent passage over an urban industrial region. The discovery of other halocarbons, accidentally revealed by the analysis, although scientifically interesting, was not the prime motive. So the literature on this topic gives the unintended impression that the FCCs are the predominant chlorine carriers in the atmosphere. In fact they are less abundant than other halocarbon classes and their presence might not have been discovered but for the exquisite sensitivity of the analytical method used.

Table 1 lists the observed abundances of the halocarbons at Adrigole in western Ireland in June and July 1974 in air coming from the west and in mid Atlantic aboard the research vessel Meteor in its cruise from Hamburg to Santo Domingo

Table 1 Background concentration of atmospheric halocarbons							
Site of measurements	FCCs Chlorocarbons

Concentrations including Cl equivalent all in parts per  $10^{12}$  by volume, figures within brackets are standard deviations. Note:  $CCl_2 = CCl_2$  has been characterised by retention time coincidence only.

in October 1973. Figure 1 illustrates the profile of concentration of CCl<sub>3</sub>F and CCl<sub>4</sub> in the troposphere and lower stratosphere over the United Kingdom in June 1974.

The chlorocarbons are less chemically stable than the FCCs but this seems not to hinder their transport to the stratosphere. If we assume that the abundancies listed in Table 1 are representative of the troposphere generally then the proportion of the total chlorine transferred to the stratosphere by each compound will be in proportion to their mixing ratios and chlorine contents. These proportions are listed for each compound in the third row of Table 1 and suggest a Cl concentration at the tropopause of at least  $1.4 \times 10^{-9}$ . This is more than ten times larger than the estimate of inorganic Cl for this region<sup>8,9</sup>.

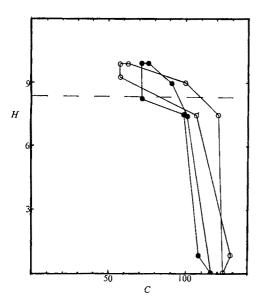

Fig. 1 Concentration (C) in parts per 10<sup>12</sup> by volume of CCl<sub>3</sub>F (●) and of CCl<sub>4</sub> (○) over central England on June 6, 1974 at heights (H) in km. - - -, Height of tropopause.

The FCCs seemingly contribute 35% of the total halocarbon chlorine entering the stratosphere. It is probable that this estimate is too high, since Table 1 lists only those compounds which have been observed. It is a commonplace for an unjustifiable significance to be attached to the easily measured quantity. It happens that the analytical method used is highly sensitive for CCl<sub>3</sub>F and CCl<sub>4</sub>. By contrast CH<sub>2</sub>Cl<sub>2</sub> and CH<sub>3</sub>Cl have not yet been sought because they are more difficult to detect. It would be sensible to determine the total organic chlorine content of the troposphere. It seems also probable that other chlorine compounds are there.

At first glance there would seem to be nothing unusual about the presence of traces of CCl<sub>4</sub> in the air. It is a typical organochlorine pollutant, a product of chemical industry. Closer investigation reveals that the origins of CCl<sub>4</sub> are tantalisingly obscure. R. L. McCarthy (personal communication) estimates that the sum total of  $CCl_4$  released to the atmosphere by all manufacturers and users of this compound does not exceed  $10^5$  ton up to the end of 1972. This quantity, had it accumulated without loss, would have given an atmospheric concentration of  $2.5 \times 10^{-12}$ . This is forty times less than the present abundance—moreover,  $CCl_4$  does not accumulate without loss; the soil, the sea and the stratosphere are all sinks<sup>5,10</sup>. There may be some unlisted or incidental production and release of  $CCl_4$  in industrial processes where chlorine encounters carbonaceous material. It seems unlikely that these unintentional sources are large; if they were it would surely be recognised, if only as a serious health hazard.

What then is the source of CCl<sub>4</sub>? Marine algae emit halocarbons<sup>5</sup> and a biological source of chlorocarbons is possible but its strength is unknown. A natural, probably atmospheric, origin of CCl<sub>4</sub> must also be considered as follows:

- The abundance of CCl<sub>4</sub> does not differ appreciably between the Northern and Southern Hemispheres<sup>5,6</sup>. This is not consistent with a northern industrial source.
- Air arriving at western Ireland shows a strong correlation between the concentration of the FCCs and Continental European origin. No such correlation is observed with CCl<sub>4</sub>.
- 3) Preliminary laboratory experiments in glass vessels show that the reaction in air between CH<sub>4</sub> and Cl<sub>2</sub> each at a concentration of 10<sup>-4</sup> results in the production of small but significant quantities of CCl<sub>4</sub>.

This evidence suggests a natural origin in the atmosphere itself. Chemical kinetics does not favour the direct gas phase chlorination of methane in the atmosphere but a heterogeneous atmospheric source is possible. If this is confirmed then other, as yet undiscovered, intermediates such as CH<sub>3</sub>Cl and CH<sub>2</sub>Cl<sub>2</sub> are likely also to be present. There is some indication from their spatial distribution that CHCl<sub>3</sub> and CH<sub>3</sub>CCl<sub>3</sub> may also in part at least have a similar natural origin to CCl<sub>4</sub>.

Molina and Rowland rightly warn of a potential hazard to stratospheric ozone should the emissions of the FCCs continue to grow unchecked but the prompt release of chlorine in the stratosphere from the other, non-FCC, halocarbons implies that the present input of odd chlorine species to the stratosphere is dominated by the simple chlorocarbons CCl<sub>4</sub>, CHCl<sub>3</sub> and CH<sub>3</sub>CCl<sub>3</sub> and so on. Indeed this input applied to the calculations of Wofsy and McElroy<sup>1</sup> indicates a 2% reduction of stratospheric ozone attributable to their presence. Unless there is some special additional effect from the release of chlorine at higher altitudes there are no grounds for singling out the FCCs as more hazardous than the other halocarbons which penetrate the tropopause.

In our paper on the distribution of halocarbons over the Atlantic<sup>5</sup> we unwisely commented: "The presence of these compounds (the FCCs) constitutes no conceivable hazard". It may be as unwise to assume that we are now at the early stages of a serious global pollution incident. We need urgently to discover the sources and sinks of CCl<sub>4</sub> and similar chlorocarbons, and also the stratospheric sinks for odd chlorine. If there is a sizeable natural chlorocarbon cycle it will give, so to speak, a stay of execution.

I thank Drs R. A. Cox, R. L. McCarthy, D. R. Parkes and C. Sandorfy for advice and the Deutsche Hydrographsiche Institut and the Captain, officers and men of the Meteor for the opportunity to sail with her.

#### Accuracy of weather forecasts

AFTER nine years of publication there has been considerable criticism of the usefulness and accuracy of long range weather forecasts. Gordon¹ has suggested that the forecasts have not yet attained a practical or economical degree of usefulness, and that advance computer technology and statistical power will not improve their accuracy unless a breakthrough in ideas is achieved. Existing methods are broadly based on an analogue or matching technique in which overall weather circulations of a particular month for many decades in the past are compared with those of the month preceding that for which the forecast is to be made.

It is, therefore, clearly necessary that various assessments of the results are made independently of those calculated by the predictors.

I have devised a classification to evaluate the accuracy of the predictions for the London area, from observations made at Kew Observatory. The portion of the long range forecast used is that part which refers to southern or south-eastern England. Although the forecasts mention several parameters, I have selected temperature and rainfall for verification (probably the two most important factors for the consumer, whether in the public or private sector of the national economy). This study deals with the 108 months from June 1965 to May 1974, inclusive.

Table 1 Assessment of official long range forecasts Predicted Good Bad Very bad Actual distribution Observed Above Temperature average 10 Ráinfall 5 31 32 22 Average Temperature Rainfall 36 38 Below 44 39 average Temperature 16 13 6 11 Rainfall

	Tal	ble 2 Scoring in systems A and B	
	forecast above below average		All forecast average
	$\begin{array}{c} 2 \times 3 = 6 \\ 1 \times -2 = -2 \end{array}$	(assuming the expected distri-	$ 2 \times -2 = -4 \\ 1 \times 8 = 8 $
A	$2 \times -2 = -4$ Total 0	bution of 2, 1, 2 in 5 trials	$2\times -2 = -4$
В	$2 \times 4 = 8$ $1 \times -2 = -2$ $2 \times -3 = -6$ Total 0		$2 \times -2 = -4$ $1 \times 8 = 8$ $2 \times -2 = -4$ $0$

The forecasts predict mainly one of three probabilities, below average, average (which includes near average or about average), and above average. A few forecasts of temperature have predicted much above average or much below average but these classifications have been treated simply as above average or below average in this study.

The boundaries which separate the classes above average, average, and below average are not published with the forecasts in the press or in the Weather Log (in Weather) and in many cases the public must make an inspired personal judgment. The Meteorological Office will, however, supply this information on request and it is understood that subscribers to the long range forecasts are provided with the exact boundaries. These are quintiles for temperature and terciles for rainfall, and are based on the climatic mean for the particular month and area of the United Kingdom for which the forecast applies. In the case of rainfall,  $\pm 20\%$  of the mean climatic total defines the

	Table 3 Sequential annual point totals 1965-74, inclusive (108 cases)

- \* 7 months.
- † 5 months.

middle tercile or band width for the average condition. In the case of temperature the middle quintile for Kew is about  $\pm 0.35^{\circ}$  C when averaged throughout the year; it is used in the forecast assessment to define the average condition.

The classification system used here to assess the forecast results considers nine boxes, three for each class of prediction. If the observed result falls in the same box as the predicted result the forecast is 'good', if in a box adjacent to the predicted result the forecast is 'bad', and if in a box two boxes away from the predicted result the forecast is 'very bad'. In the last case it means that a forecast for above or below average conditions has been made whereas the observed result has been the opposite, that is, below or above average, respectively.

Table 1 shows the results for temperature and rainfall, together with the actual distribution of observed results. The observed quintile distribution follows closely the ratios 2,1,2 where much above and much below average are included with the above and below average cases. The observed tercile distribution follows the 1,1,1 ratios acceptably well for the rainfall.

Two scoring systems may be used. The first is that applicable to a game of chance. The second is rather better for the purpose of testing a scientific prediction technique in that it gives a one point bonus for a correct above average or below average forecast and a one point penalty for a very bad forecast as already defined.

For temperature, the quintile distribution is divided into the proportions 2,1,2. The probabilities for each class above average, average and below average, respectively, are therefore 2/5, 1/5, and 2/5. These three probabilities are equivalent to odds of 1.5 to 1, 4 to 1, and 1.5 to 1, respectively (3 to 2, 8 to 2, and 3 to 2, respectively). The gains for a success are therefore 3 for above average, 8 for an average and 3 for a below average. A failure in any class loses 2 points and this is indicated by -2. That explains the scoring system if the rules of a game of chance are operated (system A).

Scoring system B is exactly the same as system A except for a modification which allows arbitrarily one point extra if a success is forecast for above average or below average. Thus, a success for above average is 4, for average 8 as before, and for below average 4. To equalise this a penalty of one point is invoked if the result is the opposite of the forecast of condition. For the latter case the loss is -3 instead of -2.

Both systems add up to zero if all cases are forecast in any one category (Table 2). The total scores for the nine-year period studied are:

Temperature: system A, -1; system B, 7. Rainfall: system A, 6; system B, 4.

None of the scores approaches an acceptable level of statistical significance as given by the chi square test for 108 cases. Wright and Flood<sup>2</sup> found no statistical significance for the temperature and rainfall forecasts in an assessment covering the results of forecasts for the whole country for a two-year period. Some statistical significance was, however, found for the general information forecasts. The latter comprise statements of the kind "soon becoming wetter", "dry weather at first", "some warm days", and so on. In view of the fact that such statements are often very subjective in character it is extremely difficult to assess the results quantitatively. For this reason, and because the predictions are often of a synoptic scale type and, therefore, not really long range forecasts, it is doubtful if the significance is meaningful in the context of a 30-d period.

The results of the long range forecasts for a month ahead for temperature and rainfall do not approach an acceptable level of statistical significance. In fact, it is doubtful whether one can honestly say that they are even marginally better than chance. Although the selected cases only represent a sample of the total population of cases which could include a further 10 areas, the London area could be considered as one of the most important for verification. Further studies on the other areas should be done but it is doubtful if the net result would show any marked improvement. Furthermore, it is extremely doubtful that Ratcliffe's claim³ of a modest but real improvement in the last few years in the long range forecasts is now valid. Table 3 shows the year-by-year scores for systems A and B for both temperature and rainfall.

It is also questionable whether the band width of  $\pm 0.35^{\circ}$  C for the middle quintile for temperature is at all meaningful as a definition of average temperature for the consumer. A band width of  $\pm 1^{\circ}$  C might be far more useful to the suppliers of gas, electricity, coal and so on, for planning purposes.

It is certainly time to consider whether the very considerable expense incurred by this branch of our National Meteorological Service should continue to support what might be judged as a profitless activity. Bearing in mind that it is recognised that there is a built-in persistence factor in the sequence of

meteorological conditions, almost any person conscious of the weather should be able to obtain a small positive score after a sufficient number of trials, given the previous months anomalies.

### Microstress mechanism for the time dependence of the modulus of crystalline polymers following an imposed change in volume

Parry and Tabor¹ have observed a significant time dependence of the dynamic shear modulus (G') of crystalline polymers at high hydrostatic pressure  $(10,000 \text{ pound inch}^{-2})$ . The modulus observed a few seconds after the increase in pressure is lower than the modulus observed at later times. There are two obvious explanations of this effect. The first is that it is due to a time-dependent bulk compliance (B). A pressure-induced reduction in volume increases G'. If B is time dependent, then the volume will also be time dependent and will continue to decrease after the increase in pressure, thus rendering G' time dependent. The second explanation is that the time dependence of G' is due to the pressure-induced generation of shear stresses in the heterogeneous solid. Of these explanations Parry and Tabor¹ favour the second. This view is supported by the following argument.

It is known that in polycrystalline solids with anisotropic thermal expansion coefficients, a change in temperature produces profound changes in both the plastic properties of the solid and the creep compliance<sup>2-6</sup>. This effect is attributed to the thermally induced generation of microstresses. The volume change of each anisotropic unit is constrained by the aggregate so that shear stresses are induced. The shear stresses relax slowly with time as the units shear. If the solid is stressed at the time of the temperature change the effective stress is the sum of the applied stress tensor and the microstress tensor and it is this combination of stresses, together with the nonlinear properties of the solid, which produces the anomalous mechanical properties.

The preceding mechanism is independent of the sign of the imposed change in volume. Evidence that this is in accord with observation is shown in Fig. 1. A specimen of linear polyethylene (Hifax 1900) was heated to 50° C and maintained at that temperature for 12 h. It was then cooled slowly to 40° C. After 10 min the temperature was increased abruptly (within 1 s) by  $\Delta T = +2.8^{\circ}$  C. A series of stress pulses (of duration 100 s) was then applied at various times after the jump in temperature. The interval between the stress pulses was sufficiently long that the strain had recovered to zero before the next stress pulse was applied. A second experiment was then performed, identical to the first in every way except that the temperature was reduced abruptly by  $\Delta T = -2.8^{\circ}$  C. Fig. 1 shows the time dependence of the observed shear strains at 40 s. 1,000 s and 6 h after the abrupt change in temperature. For both positive and negative values of  $\Delta T$  the creep strains decrease with storage time. That is to say, although the thermally induced

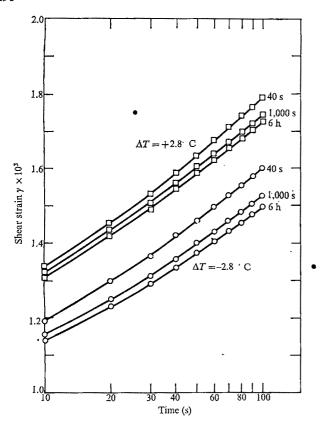

Fig. 1 Dependence of shear strain on time in successive 100-s pulse experiments for linear polyethylene showing the systematic reduction in strain with storage time for both positive and negative values of  $\Delta T$ . Temperature cycle:  $\uparrow$  50° C; 10 min;  $\Delta T$ ; pulse experiments. Shear stress  $\sigma_0 = 0.175 \text{ N mm}^{-2}$ .

volume changes were positive and negative the effect of storage time is always to increase the modulus.

The preceding experiment disposes of alternative mechanisms, such as time dependence of volume. It also leads us to predict that if the interpretation of Parry and Tabor<sup>1</sup> is correct then the observed value of G' in their experiments will always increase with storage time after a pressure change, independent of the sign of  $\Delta p$ . The crucial experiment will be to determine the time dependence of G' following a negative  $\Delta p$ .

It will be noted that the effect of lapse time is more marked in Fig. 1 for  $-\Delta T$  than for  $+\Delta T$ . This effect is due to the thermal history: the specimen was cooled to 40° C from 50° C. If the thermal cycle is altered in this respect alone (†50°C;  $\downarrow$  30° C; 12 h;  $\uparrow$ 40° C; 10 min;  $\Delta T$ ; pulse experiment) then the effect of lapse time is more marked for  $+\Delta T$  than for  $-\Delta T$ . The explanation is that the specimen is to some extent equilibrated for either  $+\Delta T$  or  $-\Delta T$  depending on the direction of approach to 40° C before the jump in temperature.

### Effects of non-electrolytes on the solubilities of salts in water

It was shown by Setchenow<sup>1,2</sup> that the solubility  $(s_w)$  of a non-electrolyte in an aqueous solution of salt concentration $c_s$  was given by

$$\log s_{\rm w} = \log s_0 + k_{\rm s} c_{\rm s} \tag{1}$$

where  $s_0$  is the solubility of the non-electrolyte in pure water and  $k_s$  is a constant. Deno and Spink<sup>3</sup> found that for a given salt,  $k_s$  was proportional to the characteristic volume of the non-electrolyte which in m3 mol-1 equals the parachor (calculated in the usual way4 in c.g.s. units)×10-6. The effects on the solubilities of salts in water of the addition of many nonelectrolytes is now shown to depend also on the characteristic volumes as well as on the concentrations of these non-electro-

Rothmund<sup>5</sup> found that equation (2) could be used for the solubilities of lithium carbonate in water containing non-•electrolytes where  $S_{w}$  and  $S_{0}$  are the solubilities of the salt in the solution of non-electrolyte (concentration  $C_s$ ) and in pure water, respectively. Rothmund also measured the solubilities of silver sulphate, potassium bromate, potassium perchlorate and hydrated strontium hydroxide in water and in solutions (500 mol m<sup>-3</sup>) of non-electrolytes and found that, in general, the order for the effect of non-electrolytes was the same for each salt. It has now been found that K<sub>s</sub> is proportional to the characteristic volumes  $V^*$  of the non-electrolytes and that equation (3) can be applied to the solubilities of salts in aqueous solutions of many non-electrolytes.

$$\log S_{w} = \log S_{0} + K_{s}C_{s} \tag{2}$$

$$\log S_0$$
 (a constant for a given salt)= $\log S_w + k'_s V^* C_s$  (3)

Weber<sup>6</sup> carried out experiments similar to those of Rothmund. In Table 1 the results of Weber for potassium sulphate at 298.16 K have been used and, for the non-electrolytes listed, results for lithium carbonate<sup>5,6</sup>, potassium bromate<sup>5</sup>, silver sulphate<sup>5</sup>, silver bromate<sup>7</sup> and lead sulphate<sup>8-10</sup> at 298.16 K are given. The values of  $k'_s$  used were derived from all results reported and not just from those listed in Table 1. As required. by equation (3) values of  $\log_{10} S_w + k'_s V^* C_s$  are indeed, in most cases equal to  $\log_{10}S_0$  for a given salt. Some of the solutions of non-electrolyte are quite concentrated. For equation (3) to apply, the salt should be practically insoluble in the pure non-electrolyte which, of course, should not react chemically with the salt. Rothmund<sup>5</sup> showed that silver ions complex with ammonia and with amines. From Table 1, it would seem that silver ions also combine with acetonitrile and with phenol.

### Maternal nutrition and the sex ratio at birth

Many experiments on laboratory animals have shown that the nutrition of the dam can affect both litter size and viability. An early study indicated that breeding pairs of rats fed a poor diet also had an altered sex ratio in their offspring<sup>1</sup>, but no more precise nutritional studies of this have been made. Nutritional factors have not been considered amongst the determinants of the sex ratio at birth.

Female albino mice (Tuck and Sons, Essex) aged 35 d were

divided into two weight-matched groups and fed semipurified diets: either a low fat (LF) diet or a control diet. The diets differed only in their lipid composition. The control diet contained 66 g kg<sup>-1</sup> lipid, the low-fat diet 6 g kg<sup>-1</sup>. In the control diet, 5.0% of the dietary energy was derived from linoleic acid, 1.0% from linolenic acid. In the low-fat diet 0.27% of the dietary energy was as linoleic, 0.06% as linolenic acid<sup>2</sup>.

The control diet has been shown in this laboratory to support rats and mice through three generations, the low-fat diet to

induce essential fatty acid (EFA) deficiency in rats and mice. Animals were housed at 27° C (range 26-28° C) at a relative humidity of 80% (range 70-90%).

After 12 weeks on the diet, the animals were mated with males of the same strain that had been fed a standard laboratory diet (Diet 86, Dixons Ltd). Two females were caged with each male for 7 d during which time the males received the same diet as the females. Each male was used for only one mating.

Pregnant dams were caged individually 20 d after the introduction of the male and cages examined at least once a day for the presence of litters. The experiment was repeated three

The results presented in Table 1 show that still births and cannibalism were increased and litter size reduced on the low-fat diet, a result consistent with previous reports<sup>2,3</sup>.

What has not been previously demonstrated, however, is that the marked reduction in litter size is attributable almost completely to a reduction in the number of male pups born, no significant change occurring in the number of female births. The deviation in sex ratio at birth was due to this deficit in males relative to the control group and not to any excess in females. In spite of variations in litter size, in no litter born to a female on the LF diet was there an excess of male over female births. The unlikely possibility of parthenogenesis has been suggested when such sex ratios have been observed in mice, but this has found no experimental support<sup>4</sup>. Thus, either the Y sperm were less efficacious, or male foetuses were less viable in utero. The former possibility is unlikely, as EFA deficiency lesions take a considerable time to appear in animals fed a low-fat diet<sup>5</sup> and the male mice only ate the LF diet for 7 d during mating.

Table 1 The effect of diet on the number of male and female offspring

	Mate LF	rnal diet Control		
	diet	diet	Difference	P
No. litters born	26	28	•	
No. litters stillborn*	6	1	•	P < 0.05
No. litters partly or totally cannibalised No. litters examined	12	2	*•	P < 0.01
for sex ratio	8	15†		
No. pups per litter	5.13	7.94	2.81	< 0.025
No. male pups per litter	1.25	4.00	2.75	< 0.001
No. female pups per litter	3.88	3.94	0.06	n.s.
Sex ratio (males per 100 females)	32.2	101.5	69.3	< 0.05

Significance testing by  $\chi^2$  or Student's t test as appropriate.

Dead at first examination.

†10 litters excluded because no usable litters born to LF females from that mating.

Adult male mice have a much higher EFA requirement than females. The difference is presumed to be related to the known effects of sex hormones on EFA metabolism<sup>6</sup>. Some data suggest that the sex differences are not evident prior to sexual maturity7, although this point has been contested. The results of our experiment suggest that a sex difference in the sensitivity to EFA deficiency is not only established before sexual maturity, but before birth.

Marked distortions in sex ratio in some strains of mice are known—in one study on an inbred strain a sex ratio of 62 males per 100 females was obtained, but the cause of this remains 'still obscure'4. We suggest that the possibility of an elevated EFA requirement in such strains should be investigated. Our results indicate that even in common laboratory mice, foetal deaths can apparently be related to nutrient requirement. Therefore, it is possible that those male foetuses which survived had a lower EFA requirement or were more favourably positioned in utero. We are investigating this possibility and meanwhile suggest that the selection of progeny by nutrient requirement could complicate the interpretation of multigenerational experiments involving EFA deprivation<sup>2,3</sup>.

We are grateful to the MRC and Unilever, Vlaardingen, for financial support and to Mr T. Price for technical assistance.

#### Two modes of evolution

In some ways mammals evolve much faster than most other animals. In other ways however it now seems that they evolve at the standard rate. This dichotomy is quite unexpected, but seems post facto to be predicted by a new and ecological explanation of evolution.

Table 1 lists the phenomena whose relative rates are known. Faster turnover rates (origination and extinction) for mammals are well documented1,2 and can be shown in several ways not to be a taxonomic artifact (Van Valen, unpublished). Structural innovation and complexity is difficult to quantify, but it is commonly believed<sup>1</sup> to evolve unusually rapidly in mammals. The relative rates for chromosome number and hybrid inviability are from a comparison of frogs and mammals3.

The similar rate of amino acid substitution in proteins4.5 in mammals and other organisms is a well known problem. Its supplementation here with size evolution makes the problem worse. Kurtén<sup>6</sup> found that for ordinarily studied intervals of mammalian evolution (his "Tertiary" distribution), rates of measurable characters have a central tendency of about 30 millidarwins (ref. 7). There are almost no estimates of such rates for fish, amphibians, invertebrates, protists or plants. Because growth and evolution occur largely on a proportional rather than an absolute scale, logarithmic rates are appropriate1.7.

Table 1 Two modes of evolution in mammals with their associated phenomena

associated phonomera					
Mode	Phenomenon				
Standard	Protein sequences Linear measurements (size)				
Epistandard	Origination and extinction Structural innovation and complexity Chromosome number Hybrid inviability				

For another purpose I calculated 13 rates for invertebrates from data of Newell<sup>8</sup>. Because he may have selected his examples for higher rates, I then took the first 15 suitable references from my card file of evolutionary series and calculated rates from their data. Time scales are mostly from the Geological Society of London<sup>9</sup>, Kauffman<sup>10</sup>, or the original authors. Table 2 shows the results; the rates from Newell's data are comparable to the rest.

Although there are some patterns in the rates of Table 2, as a rough estimate of the central tendency we can use the logarithmic (geometric) mean of all the 75 rates weighted

Individual values are accurate only to about a factor of 2, but presumably are unbiased.

equally. This is about 40 millidarwins, ostensibly even a little higher than the value for mammals. (The variation in both distributions, however, is large enough for no biologically real difference to be apparent.) Two previous comparisons<sup>26,27</sup> of size rates between invertebrates and mammals both gave invertebrates the higher rate, although each used less than a half dozen rates and neither noted the resulting paradox. The highest known rates of size evolution are similar for mammals<sup>6</sup> and protists<sup>28</sup>, about 20 darwins in each case (excluding human introductions).

Some mammalian structures participate in both modes of evolution and so may focus the problem. Horse teeth are an example. Their measurements evolve in the standard mode<sup>1</sup> but their patterns of enamel, dentine, and cement evolve in the epistandard mode, as judged directly but subjectively, and indirectly by the rates<sup>1,2</sup> of origination and extinction of taxa that are defined in part by their tooth pattern.

The difference between the modes clearly is not that of neutral against adaptive evolution. Measurable aspects of horse teeth are of obvious selective importance; strong natural selection has in fact been measured on them<sup>29</sup>. The degree of constancy for size evolution is nevertheless indistinguishable now from that of protein evolution, which has some more or less predictable deviations from constancy<sup>30,31</sup> and which is measured on a much grosser scale than is size evolution. The Red queen's hypothesis<sup>2,31</sup> predicts such a degree of constancy, and I have suggested<sup>31</sup>, without evidence, that fish have really evolved as fast as tetrapods.

How then to explain the epistandard mode? In the resource space<sup>32</sup> the proportion of the resources used by one species changes over evolutionary time; usually, if one species gains resources, others lose. Presumably the boundaries in the resource space between species shift back and forth, rather than there being mostly unidirectional changes. The Red queen proposes that the changes occur at a constant average rate. The rate of extinction depends on the susceptibility of the species at risk: the greater the proportion of its resources it loses, the greater the risk of extinction.

For mammals, then, the spectral threshold<sup>33</sup> of ultimately regulatory resources needed to prevent extinction is presumably lower (loss of a lower average proportion of resources causes extinction) than in most organisms. Mammals then become extinct more often than most organisms with similar fluctuations in the partitioning of the resource space. Epistandard origination rates are needed to replace the extinctions; perhaps this just involves greater survival of incipient species, which could themselves help cause the extinctions. The apparently epistandard evolution of morphological pattern is clearly consistent with this situation, as is the epistandard reshuffling of the genome. The latter effects, however, may not be necessary causal adjuncts.

And why should mammals be so susceptible to extinction, or have such a high rate of formation or survival of incipient species? There are several possible explanations, related to mammalian attributes such as the high rate at which they use energy, their apparently sharply bounded but contiguous adaptive zones, the ease with which their genomes became reorganised, or their high-level feedback systems. Whatever the resolution of this point, it is clear that phenomena related to origination and extinction rates should participate in the epistandard mode.

Thus, for a group whose taxa have a low threshold for extinction, such as mammals, some phenomena will evolve in the epistandard mode, in some sort of causal relation to this low threshold. But other phenomena will be unaffected by the causal nexus of the threshold and will evolve in relation to the standard losses and gains in resources (realised fitness). Possibly some phenomena are intermediate, and other groups are expected to participate in epistandard mode to the extent that their extinction rates are above normal.

In the zero-sum game of the Red queen each species competes, directly or indirectly, with all others, and no species ever wins;

new adversaries replace the losers. This world is stark and shifting; wherever an equal shift causes greater harm, as for mammals, we have the possibility of explaining the additional mode of evolution that occurs there.

I thank S. J. Gould, E. G. Kauffman, V. C. Maiorana, E. C. Olson, T. J. M. Schopf, and A. C. Wilson for comments.

### Honey bee communication

More than fifty years ago von Frisch demonstrated that foraging honey bees aroused the interest of potential recruits by means of a 'dance'. These experiments showed that the forager's body provides sufficient information about the odour of the food source to enable other bees to find that food in the field. In addition von Frisch demonstrated that foragers also leave odours at the food source which aid recruits in their searches<sup>1,2</sup>. Von Frisch later found that the dance also contains distance and direction information which the recruits seem able to use3,4.

Recently von Frisch's controls have been criticised and new experiments have suggested that olfactory information alone is sufficient to explain the phenomenon of honey bee recruitment<sup>5-10</sup>. These experiments, however, were also subject to criticism11,12 and have stimulated new work with improved controls for odour cues 13-16. These more recent results are still subject to the interpretation that the bees might have been using a 'locality odour' instead<sup>17</sup>. Since there is evidence that bees can use such cues<sup>17,18</sup>, interpretation of previous work is seriously complicated. The experiments reported here were designed to examine this question more rigorously.

Under some circumstances honey bees seem to interpret a bright light in the hive as the Sun and will orient their dances to it rather than to gravity. Since both dancers and dance attenders are reoriented, no misdirection occurs19. When the three ocelli are painted over, however, a honey bee becomes far less sensitive to light 20,21 and when a light of an appropriate brightness is used, foragers with painted ocelli will ignore the light and dance with respect to gravity; while untreated bees both dance and interpret dances as though the light were the Sun. If the bees use the distance and direction information in the dance, it should be possible for ocelli-painted foragers to send recruit bees to specific but incorrect locations.

Two groups of foragers were trained using Gary's technique 22. The first group served as a control to measure the degree of reorientation of the dances to the light. The ocelli of the foragers of the second group were covered with flat black enamel during training. A 650 W quartz lamp shielded by a heat-absorbing filter was used as the light source. The hive was constructed so that dances occurred only on one side of one frame. The distance of the light from the dance area was varied until the dances of the control foragers-whose ocelli were unpainted-were completely reoriented, while those of the ocelli-painted foragers were not. For 30 min before the experiments began, the light was left on to adapt the bees to its presence. It illuminated the dance area from above, that is, the direction away from gravity. Since that is the direction 'assigned' to the Sun when the dances are performed in the dark, the dance orientations were not affected. At the beginning of the experiment the light was moved to a different angle, and the solution at the ocellipainted forager station was changed to 2 M peppermint-scented

Six experimental stations similar to those designed by Renner<sup>23</sup>, and almost identical to the forager station, were set out at the positions shown in Fig. 1. Because many recruits

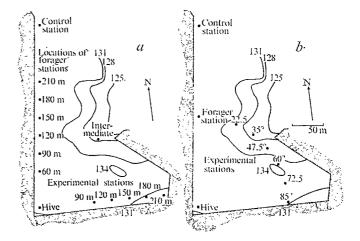

Fig. 1 Experimental array for distance and direction experiments. One group of foragers was trained on 1 M anise-scented sucrose to the control station 300 m to the north. A second group, whose ocelli were covered with paint, were trained in the same direction on 0.5 M orange-scented sucrose. Elevations are given in metres. a, Distance experiment, five experimental stations were placed in a line to the east at 30 m intervals. A sixth intermediate station was placed at the location shown, 150 m from the hive. A light in the hive caused recruits to misinterpret the dance of the treated foragers and to search for the food to the east rather than to the north. The forager station was moved every 20 min to a new location. This altered the distribution of recruits at the experimental stations (see Fig. 2). The wind was from 159° at 2 km h-1 b, Direction experiment, six experimental stations were set out at 12.5° intervals at 150 m from the hive. Every 30 min the light in the hive was moved, altering the interpretation of the dance direction. This altered the distribution of recruits (see Fig. 3). The wind was from 001° at 10 km h-1.

are hesitant to land unless they can see other bees already there, the 'flower'24 of each station was 'baited' visually with the body of an alcohol-extracted, Sun-dried bee. Each station was 'odour-baited' with the experimental solution and a wire box containing 10 anaesthetised, ocelli-treated foragers captured during training. Entering bees interrupted a beam of red light and the resulting signals from a photocell were recorded on a six-channel event recorder. The stations were filled with CO. which anaesthetised the recruited bees while they fed. Recruits arriving at and entering these stations therefore never returned to the hive to dance.

Recruits arriving at the ocelli-treated forager station were captured without the release of odours by a method described previously<sup>13</sup>. Wind speed and direction were automatically recorded while other weather parameters were monitored every 10 min. The dances of both control and ocelli-treated foragers in the hive were measured from video recordings, and the visits of treated foragers to their stations were recorded.

The first experiment was performed to determine whether information about distance is conveyed by the dances. The light was moved 85° to the left of vertical. As a result the dances of the foragers with painted ocelli were 85° to the right (clockwise) of those of the reoriented control foragers, and would therefore be expected to misdirect untreated bees to the right ' by 85°. The experimental array was located 85° to the right of the forager station (Fig. 1a). The forager station was moved every 20 min to a new distance in the following order; 90 m, 120 m, 150 m, 180 m, 210 m, 150 m, 90 m, and 60 m. Recruits arriving along the experimental array did show a preference for the distance indicated by the dance (Fig. 2).

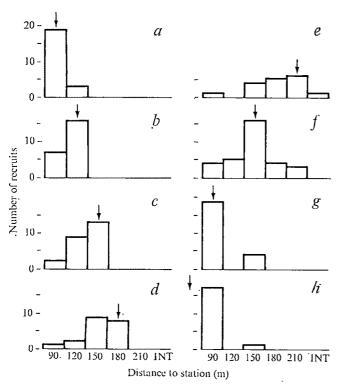

Fig. 2 Results of the distance experiment. The number of recruits captured at various distances from the hive along the experimental array is shown for each location of the forager station. The distance of the forager station is indicated by the arrow (in h the distance was 60 m). Each bar graph represents a 20 minute interval.

The second experiment was performed to determine whether directional information is communicated by the dance. The light was moved every 30 min, first 85° to the left of vertical, then to 35° left, and then to 60° left. The control foragers were reoriented by the same amount, so the recruits would be expected to misinterpret the dances of the treated foragers by a

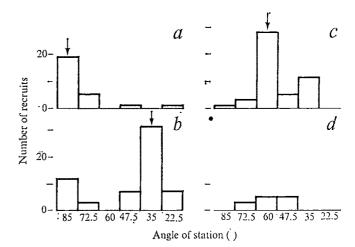

Fig. 3 Results of the direction experiment. The number of recruits captured in various directions from the hive is plotted for several orientations of the light. The arrow indicates the direction which the treated foragers signalled to untreated recruits. The timeintervalis 30 min. In d the light was moved to the 'up' position and the forager food removed.

corresponding angle to the right. The experimental array was composed of six stations arranged at 12.5° intervals and 150 m from the hive (Fig. 1b). The recruits arriving at the experimental stations did show a preference for the direction expected from the dance (Fig. 3).

Since most of the recruits arrived at locations specified by the dances, but not near the site being frequented by the foragers performing those dances, olfactory information unique to the forager station or its locale does not explain recruitment. Under these conditions the dance clearly communicates abstract distance and direction information which many recruits are subsequently able to use.

Additional details of this technique, these experiments and the results of subsequent experiments will be reported elsewhere. I thank Donald R. Griffin, Peter Marler and Fernando Nottebohm for their criticisms of this manuscript. Financial support was provided, in part, by the Cary Trust, Millbrook, NY.

### Erythropoiesis in a cell population from the early chick blastodisc induced by diffusible product of second cell population

Onset of rapid haemoglobin formation in the blood islands of the developing chick blastodisc, both in ovo and in vitro, commences at the stage of the 6- to 7-somite embryo<sup>1</sup> which is normally attained after 28-33 h of incubation. This phase of haemoglobin formation seems4,6 to reflect a previous covert differentiation of erythroid-progenitor cells distinct from pre-existing erythropoietic cells which form small quantities of haemoglobin as early as the primitive streak stage of development—after about 20 h incubation<sup>5</sup>.

We have recently developed procedures for the isolation from dispersed single-cell suspensions of primitive streak and head-fold blastodiscs of two distinct cell populations which form foci of erythropoiesis readily visible to the naked eye when incubated as cell reaggregates. One of these populations was further resolved into two discrete essential subpopulations. Aggregates of either of the individual subpopulations tested singly formed no detectable haemoglobin, whereas aggregates formed by remixing portions of the resolved subpopulations were strongly erythropoietic<sup>6</sup>.

As a first approach to defining the nature of the interaction between these two subpopulations we have now determined that direct contact between them is not required. Rather, one of the subpopulations contains progenitors of cells of the erythropoietic series which differentiate into erythroid cells in response to diffusible product(s) of the complementary subpopulation.

Blastodiscs of the Shaver Starcross No. 288 line of White Leghorn fowl were explanted on to a solid minimal medium<sup>3</sup> and those at the primitive streak and head-fold stages of development were selected for these experiments. They were detached from their supporting vitelline membranes and dispersed by incubation with gentle agitation for a total of 20 min in 125 µl per blastodisc of minimal medium containing 40 units ml-1 of collagenase (Sigma Chemical Company, Type I) and 50 units ml<sup>-1</sup> of hyaluronidase (Sigma Chemical Company, Type I). Dispersion was facilitated by gentle flushing with a Pasteur pipette at 10 and 20 min of incubation. Suspensions of single cells were recovered by filtration through one layer each of Nitex No. 73 (Thompson and Co., Montreal) and Nitex No. 53 nylon monofilament cloth.

Volumes (1.2 ml) of suspension containing  $1.2 \times 10^7$  cells ml<sup>-1</sup> were layered on to freshly-prepared, sterile discontinuous density gradients of Ficoll in liquid minimal medium, at room temperature. These consisted of a 1.3 ml upper layer of solution of specific gravity 1.044, a 1.3 ml intermediate layer of specific gravity 1.049, and a 1 ml cushion of specific gravity 1.062. These gradients were immediately centrifuged in Spinco SW 50 rotors at 4,500 r.p.m. for 30 min without braking. Cells retained at the upper (subpopulation A) and lower (subpopulation B) interfaces, respectively, of the upper Ficoll band of the gradient were each transferred to 5 ml of minimal medium -2% foetal calf serum (Gibco, Grand Island, New York) and sedimented at 5,800g for 10 min.

The pellet of subpopulation A was plated with a sterile microspatula on a portion of vitelline membrane laid on the surface of egg homogenate medium, freshly prepared and prewarmed. A layer of dialysis membrane sterilised by autoclaving in distilled water, then equilibrated with Earle's minimal medium containing HEPES buffer (Gibco, Grand Island) and 20% foetal calf serum, was placed over this aggregate and extending beyond it for at least 2 cm on all sides. The pellet of subpopulation B was then plated on the dialysis membrane, and the whole was incubated at 38° C in a moist chamber.

At 4 d the upper aggregate of subpopulation B was

seen to be 'peppered' throughout with foci of erythropoiesis readily visible to the naked eye. By contrast, neither the lower aggregate of subpopulation A nor control aggregates of subpopulation B plated alone on dialysis membrane contained any visible haemoglobin.

This result clearly establishes that the two resolved cell populations play different roles in the differentiation of cells of the erythropoietic line. Moreover, they demonstrate that the progenitors present in subpopulation B differentiate to erythroid cells in response to diffusible material(s) of low molecular weight produced by cells in the complementary subpopulation A.

Miura and Wilt<sup>8</sup> have previously demonstrated that haemoglobin formation in cells of the mesodermal layer of the primitive chick blastodisc is dependent upon material from cells of the endoderm layer which can diffuse through a Millipore filter. It is therefore tempting to suppose that the essential cells of our subpopulations A and B are derived from the endoderm and mesoderm, respectively. The relationships between the resolved subpopulations and those inferred to be present in the intact blastodisc however remain to be established.

### Preparation of human placental villous surface membrane

THERE is currently considerable interest in the mechanism of protection of the foetus against rejection by the mother. Various theories have been put forward to explain this phenomenon, including the existence of an immunologically inert barrier between mother and foetus2, and a reduction of immunological reactivity of the mother during pregnancy3. A further possibility is that a hormone such as progesterone binds to the external villous surface of the placenta and masks its antigenicity.

The surface membrane of human chorionic villi represents the effective foeto-maternal junction and therefore a preparation of this membrane would be of value in studying the immunochemistry of the foeto-maternal relationship. We have used a simple saline extraction technique to remove this material from placenta and have studied its composition by electron microscopy. It is likely to contain any antigenic material present as a somewhat similar technique (hypotonic solutions, 0.1-0.8%) was used by Davies4 in the preparation of membrane fragments rich in H-2 antigenic activity from cell surfaces of mouse spleen and thymus.

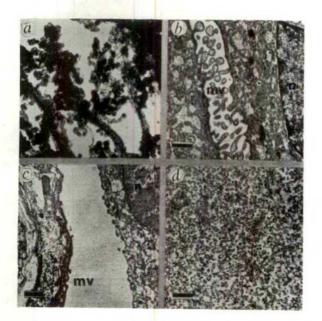

Freshly delivered normal human placentae, whose normality was subsequently confirmed by histology, were used. Preliminary experiments using solutions of varying composition and ionic strength established the optimal conditions. In the procedure finally adopted, a 10-20 g tissue sample is spread out manually and then washed rapidly, first in ice-cold isotonic CaCl2 solution and then in ice-cold Kreb's physiological saline. This removes much of the blood from the intervillous spaces. The sample is next placed in ice-cold 0.9% NaCl solution and gently agitated at 0° C for 30 min using a magnetic stirrer. During this procedure, the chorionic villi spread out so that their surfaces are well irrigated (Fig. 1a). The saline wash is then poured off and centrifuged for 10 min at 800g to remove fragments of tissue and red blood cells. The resulting cloudy supernatant is centrifuged in a Beckman Spinco at 10,000g for 5 min to remove larger particles and intracellular debris. Then a higher speed run (100,000g for 60 min) yields a pale jelly-like pellet.

For electron microscopie examination, three samples were taken: intact untreated placental tissue, tissue stirred with 0.9% NaCl solution for 30 min and the pellet obtained by centrifuging the NaCl wash at 100,000g. Each sample • was placed in 3% glutaraldehyde in buffered solution as

quickly as possible.

Examination of untreated tissue kept at 4° C for 40 min and compared with tissue fixed immediately (Fig. 1b), established that no significant deterioration takes place in that time but a striking loss of microvilli was seen in tissue washed with 0.9% NaCl solution (Fig. 1c). It was apparent on scanning several samples of the treated tissue, that many of the chorionic villous surfaces were free or almost free of microvilli and that no other significant changes had occurred, indicating that there had been little or no cellular damage except that due to removal of microvilli. The sedimented pellet (Fig. 1d) contained mainly membranebound bodies resembling microvilli. The material removed at 10,000g consisted of larger particles, probably consisting of intracellular fragments from damaged areas.

Preparations of the pellet of microvilli contained a high

a, Wet mount of chorionic villi floating in saline Fig. 1 a, Wet mount of chorionic vilil noating in saline  $(\times 60)$ ; b, Two adjacent villi before saline treatment; c, after saline treatment; d, 100,000g pellet. Samples for b, c and d were fixed in 2.5% glutaraldehyde in sodium cacodylate buffer, secondarily fixed with 1% osmic acid, dehydrated and then embedded in Araldite. Ultrathin sections were stained with uranyl acetate and lead citrate. Bars represent 1 μm in b, c and d. n, nucleus; mv, microvilli.

percentage of water (85-90%). Protein<sup>5</sup>, carbohydrate<sup>6</sup>, sialic acid<sup>7</sup> and lipid were also present. The progesterone content of the pellet was relatively high (2-5 µg per g wet weight which is significantly different (P=0.001) from that of whole placental tissue (1-2 µg per g wet weight)). Progesterone was estimated by gas-liquid chromatography after purification of the lipid extract by thin-layer chromatography on silica gel.

Work is now in progress on the nature of the association of progesterone with the villous surface of the placenta, as represented by the pellet of microvilli. After solubilisation by 1% sodium deoxycholate, the product is incubated with radioactive (1, 2-3H) progesterone and is then fractionated by ion exchange chromatography, gel filtration and

polyacrylamide gel electrophoresis.

We believe that the material removed from placenta by the treatment described consists of microvilli and related membrane fragments, and the evidence for this is the appearance of the detached particles and the fact that the tissue left behind is essentially normal under the electron microscope. The preliminary chemical examination of the

pellet is compatible with this view.

The procedure outlined above is simple, rapid and gives a good yield of material. Apart from further studies on the immunology of the foeto-maternal interface, it should also be a useful experimental preparation for general investigations on the biochemistry of cell surface antigens, membrane-bound enzymes and other membrane components. In view of the extremely marked degenerative changes in the trophoblast which are often seen in pre-eclampsia and sometimes in certain other disorders of pregnancy it may be useful to use this technique in the study of these conditions.

We thank the Medical Research Council for a research grant and Peter Seal for help in the earlier stages of this work.

### The effects of mitomycin C on remyelination in the peripheral nervous system

REMYELINATION within the central nervous system (CNS) is rarely seen in pathological material or in experimentally produced lesions and when it occurs it is a considerably slower process than its counterpart in the peripheral nervous system. It is generally thought that a major factor precluding central remyelination is the failure of oligodendroglia to undergo division1.2. As this hypothesis is difficult to test experimentally

in the CNS, we have attempted to mimic the situation peripherally, and have examined the effects of inhibiting Schwann cell proliferation after peripheral demyelination. Here we report our preliminary results.

This type of experiment is feasible only if the demyelination is not accompanied by destruction or injury of Schwann cell or axon, and a reasonably specific means of blocking cell division can be used in which side effects are minimal. We have shown previously that the intraneural injection of lysophosphatidyl choline (LPC) into the sciatic nerve of the adult mouse will produce a circumscribed demyelinating lesion, without producing detectable damage in either Schwann cell or axons<sup>3</sup>. Mitomycin C inhibits DNA replication<sup>4</sup> and has been used successfully to inhibit cell division in early frog embryos<sup>5</sup>.

In the first experimental series, adult mice received intraneural injections (about 2 × 10<sup>-4</sup> ml) of a solution of mitomycin C (400 µg<sup>-1</sup> ml in physiological saline), followed 24 h later by a solution of LPC (10 mg ml<sup>-1</sup> in physiological saline) (ML24 animals). Animals were killed at various intervals after the I•PC injections, and the nerves processed for conventional electron microscopy. Details of the method of injection are given elsewhere<sup>3</sup>. Controls received an intraneural injection of physiological saline followed by LPC (SL24 animals).

In a second series of mice, 1µ Ci ml<sup>-1</sup> <sup>3</sup>H-thymidine (specific activity about 5 Ci mmol<sup>-1</sup>) was injected intraneurally at intervals from 1 h to 48 d after the LPC injection; this was chased 45 min later by the intraneural injection of 12 mM thymidine. The animals were killed after 4 h. Controls received saline instead of LPC. A further group of ML24 mice received intraneural injections of <sup>3</sup>H-thymidine at various time intervals 3–20 d after the injection of LPC. Lengths of sciatic nerve were removed and either homogenised in cold 10% TCA, the residues collected on Millipore filters, washed and counted in liquid scintillation medium<sup>3</sup>, or they were stretched on card, processed as for electron microscopy, 3 µm thick resin sections cut and prepared for light microscope autoradiography.

In a third series of mice, standard intraneural injections of LPC were followed 3 or 7 d later by the intraneural injection of mitomycin C (LM3 and LM7 animals). The animals were killed 20 d after the LPC injections and the nerves processed for conventional electron microscopy.

There was an obvious behavioural difference between the ML24 and SL24 series. ML24 mice exhibited weakness of the hind limb which persisted for up to 14 week after the LPC injection; a similar weakness in the SL24 animals disappeared within the first 2 weeks.

Morphologically, the overall consequence of pretreatment with mitomycin C was a retardation of those changes which occur subsequent to LPC-induced demyelination. Thus, in ML24 mice the Schwann cells remained laden with debris for 2–3 weeks, while in the SL24 mice most of this debris was extruded from the axon-associated Schwann cells and taken up sequentially into supernumerary Schwann cells<sup>6,7</sup> and endoneurial macrophages within the first 10 d. There was a marked

4 h thymidine ur

10

Time after LPC

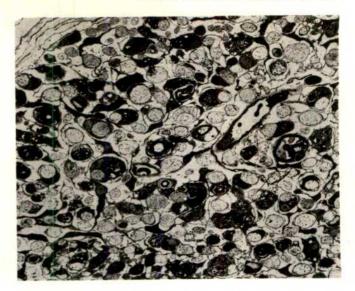

Fig. 1 ML24, 20 d after injection. There has been no remyelination (×980).

increase in Schwann cell number 6–10 d following demyelination in SL24 mice; there was little increase in Schwann cell number in those animals pretreated with mitomycin C, although in both groups there was an increase in the numbers of haematogenous cells and of fibroblasts. The relative uptake of <sup>3</sup>H-thymidine by SL24 and ML24 nerves indicated that most of this increase in cell number in SL24 mice was due to local cell division (table 1).

In SL24 mice, remyelination was established in at least 80% of the fibres by 20 d, with a concomitant maintenance of the high endoneurial nuclear count, reflecting the persistence of numerous axon-associated and supernumerary Schwann cells (about 15% of the axons were associated with Schwann cell nuclei)7. In ML24 mice, however, the Schwann cell nuclear count remained low during the first month after injection (4% of the axons were associated with Schwann cell nuclei, a figure within the limits for normal nerve). Transverse sections of ML24 nerve during this time revealed many axons to be incompletely surrounded by fine processes of Schwann cell cytoplasm, while others (about 25% of the total axonal population in some cases) appeared not to be associated with a Schwann cell. In all cases, the axons, with or without a Schwann cell, were enclosed by a continuous basal lamina. There was no evidence of remyelination (Fig. 1), although in a few Schwann cell/axon units in ML24 mice complex infoldings of Schwann cell plasma membrane were observed, unrelated to the enclosed axon, reminiscent of aberrant mesaxons in neonatal nerve. It is possible that these represented unsuccessful attempts at remyelination.

In ML24 mice many axons exhibited morphological features not normally observed in the axoplasm of normal or remyelinat-

uptake)

ing axons: large masses of myelin debris, often filling 80% of the axonal cross sectional area (Fig. 2), a proliferation of smooth endoplasmic reticulum, and numerous ribosomes. Intra-axonal lamellar debris was observed most commonly during the first 3 weeks after injection.

During the acute phase (1-20 d) of the response in ML24 mice, the morphology of the fibres 1 cm distal to the lesion was examined routinely in 1 µm resin sections, and found to be normal in 90% of the mice: however, in 10% some fibres appeared to be undergoing demyelination or Wallerian-type degeneration. In ML24 mice, 200 d after LPC injection, not only had remyelination occurred throughout the site of the lesion, but most fibres distally exhibited short thinly myelinated internodes indicating that they had also undergone demyelination and subsequent remyelination. It is possible that the proliferation of Schwann cells distal to the lesion is a compensatory response, provoked by chronic alterations in the Schwann cell/axon relationship.

In both LM3 and LM7 mice, the progress of the lesion was intermediate between that in the SL24 and ML24 animals. This is compatible with the hypothesis that it is the initial or early cell divisions which are critical in reactivating the myelinating activity of the Schwann cell.

Although in general these experiments support the idea that mitomycin C acts primarily by inhibiting DNA replication and thus cell division, its possible effects at the level of transcription must not be ignored. This aspect of mitomycin C action is being investigated.

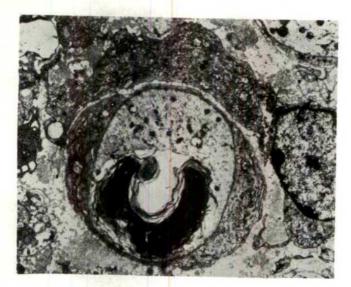

Fig. 2 ML24, 20 d after injection. Note the myelin debris in the axon  $A (\times 7,350)$ .

We conclude that the time course of the cellular response in the peripheral nervous system after the inhibition of satellite cell division at the time of a primary demyelinating episode closely resembles that found in the CNS after demyelination, that is, a slow removal of myelin debris and a failure of early remyelination. This suggests that the converse experiment, a stimulation of oligodendroglial division following primary demyelination in the CNS might lead to a more successful regenerative process

We thank the Clinical Research Fund, Guy's Hospital Medical School, and the Multiple Sclerosis Society (N.A.G.), for financial assistance during the progress of this work. We also thank Mrs J. Broadbent and Mrs S. Smith for technical assistance.

### Phagocytosis by pigment epithelium of human retinal cones

AUTORADIOGRAPHIC studies of vertebrate retinae indicate that rod outer segment disks are continuously manufactured at the base of the outer segment1.2. The disks are slowly displaced towards the tip of the outer segment, where they are shed and phagocytosed in groups by the apical processes of pigment epithelial cells3.4. Identical autoradiographic studies indicate that cone disks are not continuously manufactured at the base of the outer segment, leading to the conclusion that they are not phagocytosed<sup>5</sup>. The observation that phagosomes occur within the pigment epithelial cells of the rod-free region of human foveola, however, suggested that outer segment disks from foveal cones are phagocytosed6. Are human foveal cones uniquely rod-like in this respect, just as they are rod-like in their form and in their extension to the pigment epithelial surface, or are the disks of all human cones phagocytosed by the pigment epithelium? Our observation of a close association between cone outer segments of cat retina and pigment epithelial cell processes7 suggested an answer. As with human extrafoveal cones, those in cat do not reach the pigment epithelial surface; instead, long leaf-like processes extend from the pigment epithelium to the outer segments. These cell processes form a multilaminar sheath around the external one-third of the outer segment. If these processes engage in phagocytosis, phagosomes containing groups of cone disks should be observed within their cytoplasm and in good sections there should be very little chance of confusing them with phagocytosed rod disks. In human retinae, where cones are more plentiful than in the cat, the extrafoveal cone outer segments are also closely associated with long pigment epithelial processes 8-11. We report here that these processes phagocytose groups of disks from the cone outer segements.

The retina used for this study was obtained from the left eye of a 5-yr-old patient with an orbital rhabdomyosarcoma. The eye did not show any pathological changes. Immediately after surgical removal, the eye was transected into anterior and posterior segments and placed in fixative. The posterior segment was then dissected to isolate the macular region (Fig. 1). Sections were cut (1 µm) for orientation purposes, stained with basic fuchsin and methylene blue and examined with a Zeiss photomicroscope. Ultrathin sections were cut from the aligned specimen, stained with uranyl acetate in H<sub>2</sub>O and lead citrate, and examined in a Siemens-Elmiskop 1A electron microscope.

Human extrafoveal cones are readily distinguished from the surrounding rods; cone outer segments are shorter than rod outer segments while cone inner segments are much wider than rod inner segments. Cones are also identified by long processes which reach their outer segments from the pigment epithelium. Some of these processes adjoin the cone outer segment for at least one-half of its length.

The basic features of the cone and its relation to the pigment epithelium are seen by light microscopy (Fig. 1). The pigment epithelial processes extend from the epithelial surface to occupy the space above the cone outer segment tips. Oval melanin granules occur within the processes close to the epithelial surface. There are also two irregular inclusions within the epithelial processes close to the outer segment of the cone on the left and there is at least one irregular inclusion in the processes of the cone on the right (arrows in Fig. 1). These inclusions stain like the outer segment but somewhat more intensely and may be phagosomes. Their identification as such can be made only with the electron microscope.

Of the cones surveyed by electron microscopy, at least onethird showed phagosomes within the epithelial processes. There is usually more than one phagosome within the processes that associate with a single cone, and as many as five have been identified. The cone illustrated in Fig. 2a has two phagosomes within the processes (arrows). They can be distinguished readily from melanin granules, which are usually oval and do not have a disk-like substructure. Each phagosome consists of a group of cone disks still enclosed within the cell membrane of the outer segment (Fig. 2b). The portion of cone outer segment is itself surrounded by the membrane of the epithelial processes (Fig. 2b, arrows). The disks of this phagosome (Fig. 2b) have maintained their original orientation while the disks of the other phagosome have rotated 90°. The phagocytosed disks stain more deeply than the disks of the intact outer segment.

The processes containing the phagosomes are continuous with the processes that surround the outer segment along its outer half (Fig. 2a and c). Here, the processes are directly involved in phagocytosing the tip of the outer segment. A single process may bifurcate so that it surrounds the tip (Fig. 2c, arrow). Figure 2d shows the tip of another outer segment where a pigment epithelial process has extruded a pseudopod (arrow) which traverses the outer segment and isolates a group of 40 disks from the remainder of the outer segment. Other stages in the phagocytic process also have been seen.

Phagocytosis of portions of human cone outer segments is similar to that found in human and Rhesus monkey rod outer segments. For both classes of photoreceptor the pigment epithelial processes intermittently surround and then engulf a group of disks from the tip of the photoreceptor<sup>12,13</sup>. This suggests that human cone disks also must be continuously renewed, although the mechanism of renewal may differ from that of the rod. This conclusion is supported by the observation

Fig. 1 Light micrograph of two cones. Fixation took place in 3% glutaraldehyde-paraformaldehyde, 0.2 M Na cacodylate buffer with the addition of 1% sucrose, CaCl<sub>2</sub> and KCl, pH 7.4 for 2–3 h at room temperature. This was followed by post fixation in 2% osmium tetroxide in Na veronal acetate buffer with the addition of sucrose for 2 h and then by block staining in 2% uranyl acetate with Na H maleate buffer for 2 h (dark). The tissue was dehydrated in graded acetone and embedded in Araldite. The arrows point to inclusions within the pigment epithelial processes, which are presumed to be phagosomes. Bar equals 5.0µm.

Fig. 2 a, Electron micrograph montage of a cone. Slender pigment epithelial processes, containing two phagosomes (arrows), extend to the outer segment tip. This section is somewhat atypical in that the processes are fewer in number and thinner than in the average section. b, Enlargement of phagosome closest to outer segment tip. Pigment epithelial cell membrane (arrows) surrounds a group of 62 disks. c, Enlargement of outer segment tip showing birfurcation of a pigment epithelial process (arrow). d, Outer segment tip of a different cone. A pseudopod from a pigment epithelial process extends across the outer segment isolating the 40 terminal disks. Bars equal 0.5  $\mu$ m (a, b, c); 0.25  $\mu$ m (d).

that Rhesus monkey cone outer segments regenerate after having been damaged by separation from the pigment epithelium<sup>14</sup>.

Finally, that continuous renewal of cone disks may be general in mammals is suggested by a recent description of disk shedding by the cone-like photoreceptors of diurnal tree squirrels<sup>15</sup>.

# Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder (three binders will hold the six volumes published annually), and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains. These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

### Antigenic specificity of retinal pigment epithelium and non-immunological involvement in retinal dystrophy

Organ specific antigens have been demonstrated in the retina proper and particular attention has been paid to their relation to eye disease1-7. The antigenicity of the photoreceptors has

also been demonstrated8 and its implication in the pathological process of retinal dystrophy in experimental animals and in man has been lately under evaluation 1-10. In the case of the retinal pigment epithelium (RPE), however, no conclusive evidence of its antigenicity or immunological involvement in ocular disease has so far been produced. Nevertheless this layer fulfils an important physiological role11-13 and its primary involvement in retinal dystrophy has been emphasised14-17

This study was carried out to determine the antigenicity of the RPE and to determine whether any specific autoallergic reaction to RPE may be found in retinal dystrophy in rats. RPE obtained from normal albino rabbits was grown as cellular monolayers in tissue culture; the tissue was freezedried and stored. A Dunkin Hartley adult guinea pig was immunised by six injections of 4 mg of the freeze-dried material given subcutaneously at weekly intervals together with Freund's complete adjuvant. The animal was killed at the end of the experiment and the serum was stored at -20° C until used. Several Cryostat sections of four normal eyes from albino rabbits and several primary cultures of RPE from 12 normal eyes of albino rabbits and the same number of normal eyes from Wistar albino rats, were studied by indirect immunofluorescence technique, using fluorescein-labelled anti-guinea pig serum. Cryostat sections and primary cultures treated first with normal guinea pig serum and then with fluoresceinlabelled anti-guinea pig serum were used as controls. Antibodies to RPE were present in the sensitised guinea pig serum (Fig. 1), which reacted intensely with cultured rabbit RPE and somewhat weakly with cultured rat RPE; both cytoplasmic and membranous fluorescence were observed suggesting that the antigens are located on the surface membrane as well as intracellularly. Whether or not these represent two distinct antigen systems requires further study. In whole cryostat

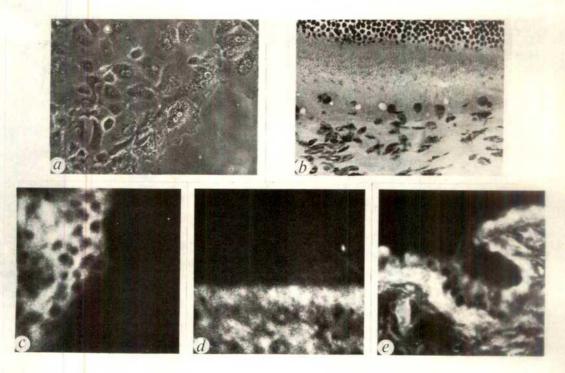

Fig. 1 Indirect immunofluorescence study of Cryostat ocular sections and RPE cultures from albino rabbits. The sections of sensory retina, RPE and choroid were cut in a tangential oblique plane; ciliary processes were sectioned anteroposteriorly. Primary explants of rabbit RPE, grown on glass, were cultured in medium 199 (Wellcome) and heat-inactivated rabbit serum (30%) to which fresh glutamine (Bio Cult) was added (300 mg per 1000 ml). Cultures on their glass coverslips were thoroughly rinsed in warm (37° C) balanced salt solution. Both Cryostat sections and primary cultures were fixed in ether/acetone before sequential incubation with sensitised or with normal guinea pig serum and fluorescein labelled anti-guinea pig serum (Wellcome); they were incubated at room temperature for 30 min and washed in a bath of phosphate buffer saline (pH 7.6) for 30 and 45 min. respectively. All sera were diluted 1:10, a, 3 day-old primary culture of rabbit RPE (phase contrast, × 82.5); b, cryostat section of retina, RPE and choroid (haematoxyin and eosin × 72.5); c, indirect fluorescence localisation in 3-day old primary culture of rabbit RPE (× 99); d, cryostat section of retina, RPE and choroid. Note the intensity of RPE fluorescence outlined as an approximately horizontal band between the non-fluorescent retina and the underlying fluorescent choroid 198); e, cryostat section of ciliary processes. Note the convoluted fluorescent layer of the pigmented epithelium upon the surface of which the non-pigmented ciliary epithelium can be observed with a background negative fluorescence. The stroma presents a weak positivity  $(\times 198).$ 

sections of rabbit eyes no fluorescence was seen in the sensory retina including photoreceptors, thus further suggesting that the RPE which develops from the outer layer of the secondary optic vesicle is antigenically distinct from the sensory retina, especially the photoreceptors, which develop from the inner layer of the secondary optic vesicle.

A positive fluorescence was, however, observed in the RPE and pigmented layer of the ciliary epithelium and also in the extravascular choroidal tissue. As the pigmented epithelium of the ciliary body is the forward continuation of the RPE it is understandable why this tissue cross-reacted with the anti-RPE serum; the fluorescence of the choroid remains unexplained but it suggests that extravascular choroidal tissue has some antigenic material in common with the RPE. As growth patterns of cultured RPE are quite different from those of cultured choroidal mesenchyme and as extreme care was taken to obtain pure RPE for tissue culture it seems highly unlikely that the materials we used for sensitising guinea pigs were contaminated with choroidal tissue, but it is a possibility which is difficult to rule out.

To investigate whether autoantibodies to RPE could be demonstrated in cases of rat retinal dystrophy, flat preparations of RPE were obtained from Wistar albino rats and inbred PETH dystrophic rats of comparable age groups. Serum was obtained from two groups of inbred PETH dystrophic rats: first, animals of approximately 3 weeks of age showing early retinal degeneration and, second, animals of 1.5–2 months of age showing marked retinal degeneration. Indirect immuno-fluorescence study using fluorescein-labelled anti-rat immuno-globulin serum failed to demonstrate any antibodies against RPE in dystrophic animals.

For the first time it has been possible to demonstrate the antigenicity of the RPE and it seems that the antigen present within it is quite distinct from those present in the visual cells of the retina, but no evidence was obtained that this plays a role in retinal dystrophy of the rat.

We thank Professor Norman Ashton, for his advice and criticism, and Miss E. Robins, Mr R. Alexander and Mr G. Otiko, for technical assistance.

### X-ray dose response for mutation to fructose utilisation in cultured diploid human fibroblasts

THE majority of studies relating to somatic cell mutation in cultured mammalian cells have been performed with established (heteronuclear) mammalian cells2. There are important karyotypic and metabolic differences, however, between cultured heteronuclear cells and mammalian cells in vivo and mutation in cultured diploid (homonuclear) cells may be more relevant to the in vivo situation. Mutation, in the broadest sense of the term1, has been studied in cultured diploid cells2-9 and there is evidence, from the work of Albertini and DeMars2 with 8-azaguanine resistant (Agr) variants of diploid human fibroblasts, that it may be possible to quantify radiation-induced mutation in diploid mammalian cells. Here we report that the utilisation of fructose, in place of glucose, as the major carbon and energy source, was used as a phenotypic character for mutation studies with a culture of diploid human fibroblasts. Although not yet fully understood, the fructose-utilisation mutation system does circumvent some of the problems of mutation expression time associated with the selection of •Agr variants of cultured mammalian cells.

Early passage HF10 diploid human fibroblasts (6-25 generations in vitro) grew to confluency when the hexoses D(+) galactose or D(+) mannose replaced D(+) glucose as the major carbon and energy source in Eagles minimal essential medium (MEM) containing 10% dialysed foetal calf serum (MEMFCS). The hexose,  $\beta D(-)$  fructose, did not replace

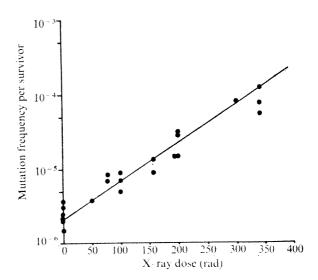

Fig. 1 X-ray dose-response for induction of fructose-utilising variants of 6-25 generation HF10 diploid human fibroblasts. Each point represents between ten and twenty variant clones scored. HF10 diploid human fibroblast cultures were initiated from 3 embryonic limb tissue and maintained in monolayer culture at 37° C using methods previously described12. for mutation induction experiments were trypsinised from culture vessels during the exponential phase of growth and resuspended in hexose-free growth medium (Eagles minimal essential medium (MEM) plus 10% foetal calf serum, Flow Laboratories, Irvine, Scotland). Cells were irradiated in suspension with varying doses of 250 kV X rays, dose rates varying between 50 and 250 rad min<sup>-1</sup>. Immediately after irradiation  $2 \times 10^5$  cells were added to each 9 cm tissue culture grade Petri dish (Sterilin, Richmond, Surrey, England) which contained 10 ml glucose-free MEM containing 1 mg ml $^{-1}$   $\beta D(-)$  fructose (Sigma, Kingston, Surrey, England) plus 10% dialysed foetal calf serum. The serum batch used in these experiments was dialysed for 4 h at 4° C against 100 volumes of 0.85° NaCl. Petri dishes were incubated at 37° C in CO2 enriched air for 14 d and variant clones arising in the fructose medium were stained for 1 h with 0.25% Azur A stain (Searle Diagnostic, High Wycombe, England). Mutation frequencies after X-irradiation were calculated with respect to the fraction of cells surviving each dose and the dose-response curve drawn by eye through the data points.

Table 1 Distribution of clones utilising fructose amongst Petri dishes containing irradiated and non-irradiated HF10 cells.

$ \begin{array}{cccccccccccccccccccccccccccccccccccc$	futation frequency per survivors 3.1 × 10-6 7.1 × 10-6 2.8 × 10-6 7.5 × 10-8

Minimum estimate not corrected for efficiency of recovery of clones<sup>2</sup>.

glucose as a carbon and energy source and HF10 cells degenerated in fructose MEMFCS at the same rate as they did in hexose-free MEMFCS. Limited growth of HF10 cells occurred in hexose-free MEMFCS unless the foetal calf serum (FCS) added to the growth medium was dialysed to reduce the concentration of glucose in the serum.

With the optimum number of HF10 cells  $(1 \times 10^5-2 \times 10^5)$  in 9 cm tissue culture grade plastic Petri dishes containing 10 ml fructose MEMFCS, fructose-utilising (Fruc<sup>+</sup>) clones arose at a spontaneous frequency of approximately  $10^{-6}$ . As no clones were seen when fructose was omitted from the medium, other medium or serum components are of themselves insufficient. This observation contrasts with the work of Varshaver et al.<sup>9</sup> who found that human diploid fibroblasts selected by their ability to grow in a fructose medium were probably dependent for growth on other medium or serum components.

Three Fruc<sup>+</sup> clones isolated from HF10 cultures were karyotypically normal, had stable phenotypes during ten generations *in vitro* and were able to grow to confluency with glucose or fructose as a major carbon and energy source. Two Fruc<sup>+</sup> variants that were tested were also biochemically distinguishable from the parental strain HF10 cells; both Fruc<sup>+</sup> clones exhibited a marked increase in the rate of uptake of <sup>14</sup>C-fructose and <sup>14</sup>C-glucose (R.C., and W.K.M., unpublished) Preliminary mutation fluctuation tests<sup>4,7,9</sup> showed that Fruc<sup>+</sup> phenotypes arose in a random fashion in parallel unselected HF10 cultures, independent of the selective growth conditions. These observations alone, however, are insufficient to enable us to comment upon the genetic basis of Fruc<sup>+</sup> variants of diploid human fibroblasts.

Preliminary experiments with X-irradiated cultures of HF10 showed that the frequency of the Fruc+ phenotype amongst survivors was greater than that observed in unirradiated controls. Mutation expression time experiments were performed, with varying periods of post-irradiation growth in non-selective medium (glucose MEMFCS) before transfer of the cells to fructose MEMFCS. The maximum yield of radiation-induced Fruc+ clones was found when the cells were transferred to fructose medium immediately after irradiation, showing that the Fruc+ phenotype was fully expressed at zero expression time<sup>10</sup>.

The X-ray dose-response curve for the induction of the Fruc+ phenotype, when irradiated cells were plated in fructose medium immediately after irradiation, is shown in Fig. 1. The mutant frequency per surviving cell was cumulative and increased approximately exponentially with dose from  $2.0 \times 10^{-6}$  at zero dose to  $1.0 \times 10^{-4}$  at 350 rad. There was no absolute increase, however, in the number of mutant clones per Petri dish (Table 1), and this ratio showed no significant change with dose. This result could indicate a chance coincidence, that is, that the rates of cellular mutation and inactivation were approximately the same over this dose range. Another possible explanation of the findings is that the Fruc+ variants were more radioresistant than the parental strain, and that the radiation. rather than the growth medium, was selecting the variant clones. This seems unlikely because cell cultures grown from two of the Fruc+ variants had X-ray survival curves similar

to that of an HF10 parental culture of comparable generation number (Fig. 2). A further possibility that the Fruct variant detected in irradiated cultures were not induced by the radiation but arose spontaneously during the growth and division cells surviving the radiation is also unlikely as the cell were plated into selective medium immediately after irradiation thus allowing no time for spontaneous Fruct variants to arise from the growth and division of non-variant surviving cells. The preliminary conclusion is therefore that Fruct variant were induced by ionising radiation and that the dose-responsibility was approximately exponential.

Albertini and DeMars<sup>2</sup> found that, like the Fruc<sup>+</sup> variant reported here, Ag<sup>r</sup> variants of diploid human fibroblasts als did not show an absolute increase in number after X-irradiatio but did show a dose-dependent increase in mutant frequenc per surviving cell. An essentially similar result has been of tained independently in this laboratory with Ag<sup>r</sup> variants c HF10 cultures but because a post-irradiation growth period c ~3 d in non-selective medium was necessary for optimur recovery of Ag<sup>r</sup> clones, the interpretation of any dose-respons curve must be complicated by the problem of spontaneou mutation of survivors. The Fruc<sup>+</sup> variants, with an apparen zero mutation expression time, may therefore provide a technically more straightforward mutation system.

If the failure to demonstrate an absolute increase in mutan number with dose reflects the relatively poor mutagenicity of X rays in diploid human fibroblasts, N-methyl-N-nitro-N nitrosoguanidine (MNNG), which has been shown to be a more potent mutagen that X rays in cultured heteronuclea mammalian cells<sup>13</sup>, should give an absolute increase in mutan number with dose. Preliminary experiments with MNNC suggest that this hypothesis is correct and an absolute increase in mutant number with dose has been observed for both Agr variants<sup>2</sup> and Fruc+ variants (R.C., and W.K.M., unpublished) of diploid human fibroblasts.

Although some doubt must remain over mutation experiments that do not demonstrate an absolute increase in mutan

number with dose, the results of Albertini and DeMars<sup>2</sup> and those reported here suggest that the Agr and Fruc+ mutation systems may be useful for quantitative studies of mutation in cultured diploid human fibroblasts. It is also possible that the cumulative X-ray dose response observed with both systems is a true reflection of radiation induced mutation in cultured diploid human fibroblasts. A more complete study of the genetic basis of somatic cell variants and the phenotypic expression of induced mutation with these and other mutation systems, however, is required before dose-response curves for mutation can be interpreted with confidence.

With these experimental limitations in mind, it may be useful to compare X-ray mutation rates obtained in vitro in cultured diploid human fibroblasts and in vivo in mouse germ cells (Table 2). For dose rates between 50 and 250 rad min<sup>-1</sup> there are insufficient data to determine the shape of the doseresponse curve for mutation in mouse spermatogonia, although there is evidence that mutation induction per rad is nonlinear<sup>14</sup>. In mouse oocytes<sup>14</sup> and with both mutation systems in diploid human fibroblasts there is fairly clear evidence of a nonlinear cumulative dose-response. Mutation rates for Agr and Fruc+ variants of diploid human fibroblasts seem to be closely similar. For experiments at comparable dose rates and doses of 200-300 rad, the in vitro mutation rates in diploid human fibroblasts are also similar to in vivo mutation rates in both mouse spermatogonia and mouse oocytes. Although such numerical similarities could be misleading, it is hoped that further studies on radiation-induced mutation in cultured diploid somatic cells may help to elucidate the underlying cellular mechanisms involved in mutagenesis of normal mammalian cells in vivo.

We thank the Churchill Hospital, Oxford, for samples of foetal tissue and Drs R. H. Mole and R. J. Munson for their advice on the preparation of this manuscript.

### TRH: a possible mediator of thermoregulation

FELDBERG and Myers1 have reported that intraventricular injections of amines produce changes in the rectal temperature of unanaesthetised cats. They noted that more than 50  $\mu g$  noradrenaline produced temporary hypothermia • whilst 200 μg 5-hydroxytryptamine (5HT) induced a sustained hyperthermia. These results, coupled with earlier findings that these amines were concentrated in the hypothalamus2.3, led them to speculate that the regulation of body temperature in the cat may be mediated by the release of noradrenaline and 5HT within the hypothalamus.

Observations by other workers have raised the possibility that the ratio of cations in the hypothalamus or the release of prostaglandin E15 from the same structure may also be important for the chemical mediation of body temperature. This report concerns the effects produced when small quantities of releasing hormones, peptides also derived from hypothalamic tissue, were injected directly into the cerebral ventricles of conscious cats.

Sterile solutions of thyrotropin releasing hormone (TRH), luteinising hormone releasing hormone (LRH) and melanocyte stimulating hormone release-inhibiting factor (MIF) were injected into conscious cats in 0.2 ml artificial cerebrospinal fluid by a cannula previously implanted in the lateral ventricle. LRH and MIF were without effect on body temperature at doses up to 5  $\mu$ g. In contrast, similar doses of TRH produced a dose-related hypothermia (Fig. 1). Although the minimal effective hypothermic dose varied between individual animals, in some cats as little as 3 ng TRH produced 0.5° C fall in body temperature. At doses greater than  $0.5~\mu g$ , TRH (in common with hypothermic doses of noradrenaline and calcium) produced a sedative or quieting effect. In addition, all three peptides frequently produced defaecation and urination whilst TRH alone induced profuse salivation in some animals.

The doses of TRH needed to induce hypothermia compare favourably with the calculated TRH content of the hypothalamus<sup>6,7</sup> and stand in contrast to the fact that the quantity of noradrenaline needed to provoke hypothermia (50 µg) greatly exceeds the endogenous hypothalamic concentration of that amine2.8. Indeed, TRH seems to be the most potent hypothermic agent yet reported (Fig. 2) comparable in its potency to the hyperthermic activity reported by Milton and Wendlant<sup>5</sup> for prostaglandin E<sub>1</sub>.

The comparison between noradrenaline and TRH is also interesting from other points of view. Noradrenaline has been reported to stimulate the synthetase enzyme responsible for TRH production whilst 5HT seems to inhibit this same enzyme9. Calcium ions, known to be critically involved in the release of noradrenaline from nerve endings10,11, themselves produced hypothermia4 whilst imipramine, an antidepressant drug which inhibits the reuptake of noradrenaline into nerve endings, also produces

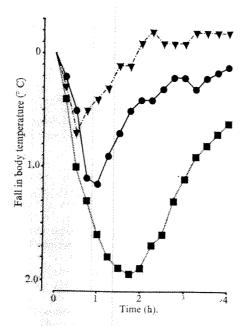

Fig. 1 Hypothermia produced in individual cats by the intraventricular injection of.  $\nabla$ , 0.05  $\mu$ g;  $\bigcirc$ , 0.5  $\mu$ g;  $\square$ , 5  $\mu$ g TRH. Drug injected at time zero.

hypothermia in cats12. Thus, it is possible to explain the hypothermia produced by all of these agents in terms of the TRH-induced hypothermia reported here.

Cooper et al.13 noticed a species difference to the effects of amines on body temperature when they found that intraventricular noradrenaline produced hyperthermia in rabbits. This observation has been confirmed by Jacob14 and is in keeping with the observation that intraventricular desipramine also produces hyperthermia in this species12 Preliminary observations in rabbits have shown that doses of 0.5 or 1.0 µg TRH injected intraventricularly produce a hyperthermia of 0.6-1.0° C.

There is speculation amongst psychiatrists as to whether TRH is an effective antidepressant agent 15,16,17. My results are consistent with the suggestion that TRH may possess antidepressant activity and may add a new dimension to

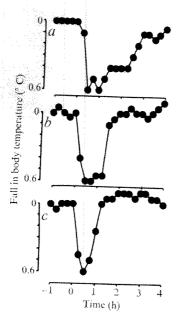

Fig. 2 Hypothermia produced in individual cats by a artificial CSF containing 20 mM excess  $Ca^{2+}$ ; b, 50  $\mu g$  noradrenaline; c, 10 ng TRH. All drugs were injected at time zero.

the amine theory of affective disorders18 in that the amines may act indirectly by their effects on TRH production. Whether this is proven or not, the present results certainly indicate that TRH needs careful evaluation as a possible modulator of mammalian thermoregulation.

### A merozoite vaccine effective against Plasmodium knowlesi malaria

Plasmodium knowlesi malaria is uniformly fatal in rhesus monkeys1. If infections are initially controlled with drug therapy, however, a degree of immunity can be induced associated with periodic relapse and low grade infection after repeated challenge. In such resistant monkeys each recurring infection is attributable to a distinct parasite variant recognisable by the schizont-infected cell agglutination (SICA) test2. Antigenic variation therefore seems to be an important mechanism determining chronicity of infection3 and complicates any attempt to achieve effective immunoprophylaxis'. Rhesus monkeys have been vaccinated with formol-treated\*, or freezethawed' erythrocytic schizonts of P. knowlesi or fractions of these parasites<sup>8,9</sup> in complete (FCA) or incomplete (FIA) Freund's adjuvant. Such vaccination reduced mortality to about 50% after challenge with the homologous variant; in surviving monkeys parasitaemia reached 3-10%, but parasites were completely eliminated after about 2 weeks and some animals were then resistant to heterologous challenge7. When the first challenge variant was known to differ from that used for immunisation, all monkeys suffered fatal infections'. The protection achieved always required the use of complete adjuvant, but this alone was inactive.

\*W, Walter Reed strain; N, Mill-Hill ('Nuri') strain of *P. knowlesi*. Numbers denote distinct variants differentiated by the SICA test<sup>2,17</sup>. †Parasitaemia on the day before death or drug cure.

Studies on the mechanism of acquired malarial immunity in vivo<sup>10</sup> and in vitro<sup>11</sup> indicated that protective antibody does not affect intracellular parasites, but interrupts the cycle of development at the stage when merozoites are released into the plasma. In addition, immune serum agglutinated free merozoites and prevented their attachment to receptors present on the red cells of susceptible species These findings suggested an important role for merozoite antigens in specific malarial immunity and prompted development of an in vitro method for isolating extracellular blood stage merozoites. Here we describe the use of these preparations for vaccination of rhesus monkeys against P. knowlesi malaria.

Monkeys (Macaca mulatta) were of either sex and weighed about 3 kg. Parasites were originally obtained from sources indicated in Table 1. Variants of P. knowlesi were differentiated by the SICA test<sup>2</sup>. Merozoite preparations (W1 variant) were isolated as described<sup>14</sup> except that phytohaemagglutinin was used in place of antiserum to agglutinate parasitised and normal red cells. The yield of merozoites was approximately 2×10<sup>10</sup> per ml of cultured erythrocytic schizonts and contamination with parasitised red cells was less than 0.1%. Two monkeys were immunised three times during 7 weeks with 1.3×10<sup>8</sup> mature schizonts (W1 variant) in FCA as controls for the schizont contamination of the merozoite vaccine. Freshly isolated merozoites suspended in 1 ml medium 199 (Burroughs-Wellcome) were emulsified with equal volumes of FCA or FIA and administered by intramuscular injection to six monkeys as shown in Table 2. Immunisation never produced a detectable infection. Immunised animals were challenged by intravenous injection of 10<sup>4</sup> or 10<sup>5</sup> immature schizonts of known strain and variant specificity on days shown in Table 2. Thick and thin blood films were examined five or more times weekly from the time of challenge. Equivalent challenge infections were administered simultaneously to normal rhesus and all suffered progressive infections. Five out of eight of the control animals died within 7–10 d and three others were cured on day 5 or 6 when the level of parasitaemia indicated a fatal outcome.

Three merozoite immunised animals were challenged first with the same variant (W1) as used for immunisation. No infection was detectable in two of these monkeys (Mz 12, 10, Table 2) and subinoculation of 5 ml of blood from one into a normal rhesus on the 11th d after challenge revealed no viable parasites (Mz 10, Table 2). One monkey (Mz 16, Table 2) challenged with W1 variant developed parasitaemia for 6 d with a maximum of 0.04%. A schizont-immunised rhesus challenged with the homologous variant showed parasitaemia for 11 d with a peak of 1.3% (cf. ref. 7). Three other merozoite immunised animals were challenged first with a heterologous variant (W3) of P. knowlesi. All showed parasitaemia which lasted for 8-12 d and did not exceed 0.07-1.5% in the individual monkeys (Mz 14, 15 and 17, Table 2). A schizont-immunised animal challenged first with the W3 variant developed a fatal infection indistinguishable from that in unimmunised controls (cf. ref. 7) (Fig. 1). Five of the six merozoite immunised animals were subsequently challenged on eight occasions during a period of up to 10 months with four distinct variants and a different laboratory strain of P. knowlesi (Table 2). Seven of these challenges did not produce a detectable infection and viable parasites could not be demonstrated by subinoculation from Mz 10 (Table 2) after challenge with three different variants during a period of about 2 months. This animal finally developed a patent infection lasting 9 d with maximum parasitaemia of 0.02% when challenged with the W1 variant 33 weeks after initial vaccination (Table 2).

In contrast to what is observed after immunisation with parasitised cells<sup>5-9</sup> or repeated infection initially controlled with drug therapy<sup>15,16</sup> these results show that challenge after vaccination with merozoites derived from a single serological variant of *P. knowlesi* leads to frequent absence of detectable parasitaemia (nine out of fourteen instances); occasional sterile immunity (shown by subinoculation in two

instances); parasitaemia of short duration (6-12 d) and relatively low intensity (maximum 0.02-1.5%) when patent infection did occur (five out of fourteen instances); resistance to several serological variants different from that used for immunisation. The available data suggest that the various schedules of vaccination employed (Table 2) provided comparable protection; we are now attempting to establish whether adjuvant is essential for merozoite vaccination. The number of merozoites was chosen arbitrarily; a smaller number might be effective, but at the level used, the in vitro cultures provide about 20 immunising doses per ml parasitised red blood cells. The induced immunity seems to be predominantly species specific since 3 merozoite immunised animals challenged with 10° P. cynomolgi bastianellii parasites developed chronic patent infections, although maximum parasitaemia was lower than in normal monkeys (Table 3). P. knowlesi infections controlled by drug therapy do not cross immunise against P. cynomolgi bastianellii<sup>17</sup> which produces chronic, non-fatal malaria in rhesus monkevs.

We conclude that merozoite vaccination protects rhesus monkeys against initial homologous or heterologous variant infection with erythrocytic stages of the normally lethal . P. knowlesi parasite. Vaccinated animals once challenged are also resistant to subsequent infection with other variants or a different laboratory strain of P. knowlesi. Merozoite vaccination induces immunity far greater in degree and significantly broader in specificity than previously achieved by immunisation or repeated infection. This form of vac-

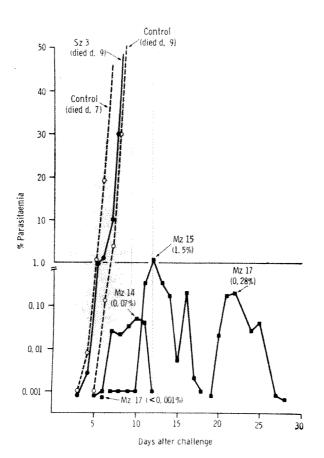

Fig. 1 Course of parasitaemia in two normal rhesus monkeys, one immunised with schizonts (Sz 3), and three immunised with merozoites (Mz 14, 15 and 17, Table 2). All animals were challenged with 10<sup>4</sup> P. knowlesi parasites (Mz 14, 15 and 17, Table 2). (W3 variant). Sz 3 had been vaccinated with a total of  $1.3 \times 10^8$  erythrocytic schizonts (W1 variant) on days 1, 41 and 77 and was challenged on day 91. To illustrate the course of low-grade infections in the merozoite immunised animals, parasitaemia (vertical axis) is shown on a logarithmic scale between 0.001 and 1.0%.

cination apparently stimulates a specific response to antigens present on a wide spectrum of P. knowlesi parasites, but poorly inductive, during natural malaria infection. Our observations are significant with regard to the development of an effective vaccine against human malaria in view of the probable existence of immunologically distinct strains of P. falciparum18,19 and the established genetic diversity of this parasite in West Africa20.

This work was supported by the Medical Research Council, London, and the World Health Organisation. We thank Miss Karen Smyth and Mr E. D. Dennis for their skilled technical assistance. P. cynomolgi bastianellii was supplied by Dr D. E. Bidwell of the Nuffield Institute of Comparative Medicine.

### Excystment by sporozoites of malaria parasites

IT is widely assumed that the mature oocyst of the malaria parasite bursts and liberates the sporozoites en masse1 although studies on the intestinal coccidians have clearly shown that the sporozoites escape through the wall of the sporocyst, a structure analagous to the oocyst of malaria parasites, by way of specialised pores2-4. During a scanning electron microscope study of the sporogonic cycle of the rodent malaria parasite Plasmodium yoelii nigeriensis in the vector Anopheles stephensi, evidence has been obtained which suggests that excystment of the sporozoite may occur by a method differing from both those described above.

Examination of oocysts on a very heavily infected gut prepared 11 d after infection revealed the presence of small holes, 0.25-0.65 µm in diameter, in the wall of some cysts (Fig. 1a). Furthermore these perforations were limited to areas some 15 µm across on oocysts 40 µm in diameter. The holes were found with increasing frequency towards the centre of this region, where larger perforations appeared. Sporozoites could be seen emerging individually through these holes. While this might have represented the early stages of the total destruction of the oocyst, evidence to the contrary was provided by the occurrence of empty oocysts in which only small regions of the cyst wall were damaged (Fig. 1b). The basal lamina of the mosquito gut epithelium lay as a diaphanous netting over the surface of most oocysts, but frequently could not be detected at all. Should this reflect the in vivo condition the basal lamina can be considered little obstacle to the escaping sporozoites.

These observations suggest that sporozoites escape through the oocyst wall by small perforations which become enlarged as emergence progresses (Fig. 1a and b). In some instances this process may be traumatic enough to destroy the oocyst. Further, it is clear there is no organelle in the wall of malaria parasite oocysts through which the sporozoites emerge, comparable to the pore occupied by the Stieda body in the sporocyst wall of intestinal coccidians.

Fig. 1 a, Scanning micrograph showing sporozoites escaping from perforated oocyst of Plasmodium yoelii nigeriensis on the midgut of Anopheles stephensi. The infection was maintained for 11 d at 25° C and 80% relative humidity. The specimen was dissected into Schneider's Drosophila medium and rinsed briefly. Following fixation in 3% glutaraldehyde in 0.1 M phosphate buffer pH 7.4 the specimen was washed in 0.15 M phosphate buffer and postfixed in 1% osmium tetroxide in 0.1 M phosphate buffer. Dehydration was in acetone. Samples were dried in carbon dioxide (using the critical point method) and gold coated in a 'sputter coater' (×°60). b, Micrograph of oocyst following the escape of the sporozoites. (×°12).

While it is recognised that the preparations examined bore unusually high densities of oocysts, and the consequent pattern of sporozoite release need not be identical to that normally seen, it is still necessary to explain both the direction and the restricted path of migration of the sporozoites through the oocyst wall. The breakdown of the oocyst could be a passive process determined by areas of weakness in the cyst wall. Alternatively the sporozoites may penetrate the oocyst actively, their orientation to areas of cyst wall that lie adjacent to the haemocoele being determined by some biochemical gradient between the surrounding haemocoelomic fluid and midgut epithelium of the

mosquito. In the present study the intimate contact of the adjacent oocysts could severely limit these areas of the cyst wall in contact with the haemocoelomic fluid.

### Evidence for energy-dependent accumulation of paraquat into rat lung

THE herbicide paraquat (N,N'-dimethyl 4,4'-bipyridilium) can produce widespread oedema and fibrosis in the human lung after accidental ingestion1-3. In those cases where death occurs after several weeks, there are no apparent pulmonary changes during the first few days following ingestion. Animal experiments in a variety of species have shown the lung to be the major target organ4-6. After administration of paraquat to animals, the lung has a high initial concentration and retains paraquat7-This retention appears to be related to the development of lung damage<sup>7</sup> (L. L. Smith and M. S. Rose, unpublished work). The mechanism of retention of paraquat by the lung is at present not understood.

We have demonstrated an energy-dependent accumulation of paraquat in slices of rat lung. This process may account for the retention of paraquat in the lungs of many species. Diquat (N,N'-ethylene 2,2'-bipyridilium), a herbicide closely related in structure and properties to paraquat, is not actively accumulated by lung slices, is not retained by the lung in vivo7.8 and does not damage the lung10 (L. L. Smith and M. S. Rose, unpublished work).

Male Alderley Park (Wistar derived) specific pathogen free rats (body weights 170-200 g) were killed with halothane. The lungs were removed and slices prepared (20-70 mg wet weight) at room temperature. Only slices with two cut surfaces were used. Incubation was carried out at 37° C in 3.0 ml Krebs Ringer phosphate<sup>11</sup> containing 200 mg% (w/v) glucose, 0.1 μCi of methyl-14C-paraquat or 0.1 μCi of ethylene-14C-diquat (Radiochemical Centre, Amersham; specific activity for both approximately 30 mCi mmol -1), and the required concentration of non-radioactive paraguat or diquat dichloride. After incubation, slices were washed by transfer to fresh medium without bipyridyl, blotted and dissolved in 1.0 ml Soluene (Packard Instrument Company Limited). Scintillator [10 ml Dimilume (Packard Instrument Company Limited)] was added and the radioactivity of the slice measured using a liquid scintillation spectrometer. 0.1 ml of media was diluted to 1.0 ml with water and the radioactivity measured after addition of 10 ml Instagel scintillator (Packard Instrument Company Limited).

The amount of diquat found in rat lung slices incubated in media containing diquat (10-5-10-3 M) remained constant from 30 min to 2 h (Fig. 1a). The plateau value obtained was dependent on the concentration present in the medium (Fig 1a). In contrast, paraquat was accumulated linearly from 30 min to 2 h (and in experiments not reported here, for up to 4 h) (Fig. 1b). The amounts of paraquat accumulated were in excess of those seen with diquat. When KCN (10-3 M) plus iodoacetate (10-3 M) were added to the medium either at the beginning of the incubation or after 1 h, this continued

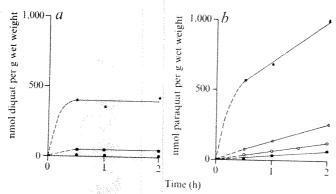

Fig. 1 The accumulation of paraquat and diquat by slices of rat lung. The medium contained the following concentration of bipyridyl:  $\bullet$ ,  $1 \times 10^{-5} \, \text{M}$ ;  $\bigcirc$ ,  $2 \times 10^{-5} \, \text{M}$ ;  $\triangle$ ,  $4 \times 10^{-5} \, \text{M}$ ;  $\blacksquare$ ,  $1 \times 10^{-4} \, \text{M}$ ;  $\triangle$ ,  $1 \times 10^{-3} \, \text{M}$ . Individual points are the mean values from four slices.

accumulation of paraquat was inhibited (Fig. 2a). Identical inhibition has been demonstrated with both 10-5 and 10-4 M paraquat present in the medium. Rotenone (10<sup>-5</sup> M) a specific inhibitor of mitochondrial respiration also inhibits uptake of paraquat (Fig. 2b). Thus, the accumulation of paraquat into slices of rat lung to amounts in excess of those seen with diquat is energy-dependent. A plot of rate of uptake (v) against the rate divided by the concentration of paraquat in the

medium is linear (Fig. 3). From these data, an apparent  $K_{\rm m}$  of  $7 \times 10^{-5}$  M and a  $V_{\rm max}$  of 300 nmol paraquat per g wet

weight per h can be calculated for this process.

After oral administration of 126 mg paraquat per kg body weight to rats, the lung concentration was shown to rise from approximately 4 µg per g wet weight at 4 h to approximately 14 µg per g wet weight at 32 h (ref. 9). During this time, the plasma concentration was constant at around 1 µg ml-1. Paraquat is removed rapidly from the blood of rats after intravenous administration7. The maintenance of a constant concentration of 1 µg ml<sup>-1</sup> for approximately 30 h can, therefore, only be the result of release of paraquat from other organs into the blood, or impaired renal function, or both. Since the gastrointestinal tract of rats was shown to contain a large proportion of the oral dose, this is the most likely source of the blood paraquat. The lung was clearly able to accumulate paraquat to levels in excess of the blood concentration. Similar experiments with diquat given orally to rats show that no such accumulation occurs (L. L. Smith and M. S. Rose, unpublished

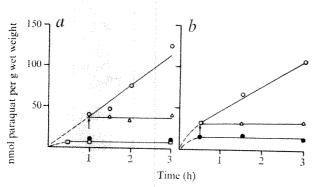

Fig. 2 The effect of metabolic inhibitors on the accumulation Fig. 2 The effect of metabolic innibitors on the accumulation of paraquat by slices of rat lung. a, The medium contained:  $\bigcirc$ , paraquat  $(1 \times 10^{-5} \text{ M})$ ;  $\bigcirc$ , diquat  $(1 \times 10^{-5} \text{ M})$ ;  $\bigcirc$ , paraquat  $(1 \times 10^{-5} \text{ M})$  plus KCN  $(10^{-3} \text{ M})$  plus iodoacetate  $(10^{-3} \text{ M})$ ;  $\triangle$ , paraquat  $(1 \times 10^{-5} \text{ M})$  plus KCN  $(10^{-3} \text{ M})$  plus iodoacetate  $(10^{-3} \text{ M})$  added at arrow. b, The medium contained:  $\bigcirc$ , paraquat  $(1 \times 10^{-5} \text{ M})$ ;  $\bigcirc$ , paraquat  $(1 \times 10^{-5} \text{ M})$  plus rotenone  $(1 \times 10^{-5} \text{ M})$ ;  $\triangle$ , paraquat  $(1 \times 10^{-5} \text{ M})$  plus rotenone  $(1 \times 10^{-5} \text{ M})$  added at the arrow. work). Thus the rat lung accumulates paraquat but not diquat both in vivo and in vitro.

Since it is known that the response of human lung to oral paraquat is delayed, it is possible that a similar accumulation process occurs in man. Therefore, it is of paramount importance that, after ingestion of paraquat, all possible measures are taken to remove paraquat not only from the stomach, but also from the rest of the gastrointestinal tract and blood.

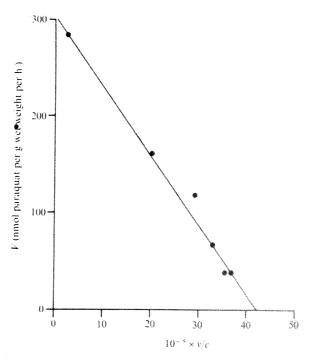

Fig. 3 The derivation of an apparent  $K_m$  and  $V_{max}$  for the uptake process.

Further work is in progress in these laboratories to investigate the mechanism of this uptake of paraquat into the lung. If the process can be inhibited in vivo it may be possible to prevent lung damage.

### Phytoalexin production by live cells in broad bean leaves infected with Botrytis cinerea

STUDIES on the role of phytoalexins in disease resistance in plants have been limited by the absence of techniques for the accurate localisation of the inhibitors within infected tissues. As a result the postulate of Müller and Börger<sup>1</sup> that phytoalexin production is confined to cells undergoing necrobiosis remains in doubt<sup>2</sup>.

The closely related phytoalexins wyerone and wyerone acid accumulate in leaves of broad bean following fungal infection<sup>3.4</sup>. Although Deverall and Vessey<sup>5</sup> suggested that phytoalexins from *Vicia faba* might be produced by healthy cells, further work by Mansfield and Deverall<sup>6</sup> led them to argue that wyerone acid production was confined to cells undergoing necrobiosis and browning. Here we report the use of fluorescence microspectrography to confirm that wyerone acid is produced by living cells in bean leaves infected with *Botrytis cinerea*.

Leaves were detached from field grown plants of broad bean cv. the Sutton and inoculated on the lower epidermis with 10  $\mu$ l droplets of sterile distilled water each containing about 5,000 conidia of *B. cinerea*, or water alone? Sites inoculated with *B. cinerea* were flecked dark brown after 2 d when droplets were collected and the underlying epidermis peeled off and stored at  $-20^{\circ}$  C. Both wyerone and wyerone acid accumulated in infected epidermal tissues but only the acid was found in inoculum droplets (Table 1). Assuming that wyerone acid in droplets originated in the epidermis the ratio of wyerone acid:wyerone produced by epidermal cells was about 21:1. The phytoalexins could not be detected in leaves inoculated with water alone.

Examination of epidermal strips by fluorescence microscopy revealed that cells that had undergone browning in response to infection by *B. cinerea* absorbed ultraviolet light but many adjacent healthy cells fluoresced blue/green. The vitality of the fluorescing cells was confirmed by their plasmolysis in 2 M sucrose and accumulation of neutral red vital stain. Fluorescence was associated with the cell vacuole. No fluorescent cells were observed in epidermis inoculated with water alone.

Both wyerone and wyerone acid fluoresce under ultraviolet light and these compounds were identified as the possible cause of the fluorescence in infected tissues by microspectrography. Examples of the almost identical spectra obtained from fluorescent cells and solutions of the purified phytoalexins are given in Fig. 1. Similar spectra were obtained for ethanolic solutions of both wyerone and wyerone acid on a standard spectrophotofluorometer (Aminco-Bowman 4–8202SPF). In view of the much greater concentrations of wyerone acid than wyerone

Table 1 Yield of wyerone and wyerone acid from inoculum droplets and underlying epidermis collected from 200 inoculation sites

	Yield (μg)			per g fresh al tissue (µg)
	Wyerone	Wyerone acid		Wyerone acid
Droplet	0	20.0	0	182
Epidermis	2.4	30.5	21.8	277
Total	2.4	50.5	21.8	459
***************************************				

All yields are the mean of results from two experiments. Epidermal tissue (0.1 and 0.12 g) was ground in methanol in a hand homogeniser. The methanol extract was evaporated to dryness in vacuo and partitioned three times between water (5 ml) and diethyl ether (10 ml). Wyerone and wyerone acid were purified from the ether soluble fraction by thin layer chromatography (TLC) on Merck silica gel precoated plates 0.25 mm thick developed in saturated tanks with diethyl ether: methanol (4:1, 8 cm run) then in dichloromethane: petroleum ether  $60-80^{\circ}$  C (2:1, 16 cm run). Wyerone and wyerone acid were detected as bands fluorescing blue under ultraviolet light (wavelength 366 nm) at final  $R_{\ell}$  0.6 and  $R_{\ell}$  0.3, respectively. After elution from silica gel with methanol the concentrations of the phytoalexins were recorded by ultraviolet spectrophotometry<sup>3</sup>. Inoculum droplets (1.1 and 0.9 ml) were partitioned three times with 5 ml diethyl ether and the phytoalexins isolated from the ether phase by TLC as described above.

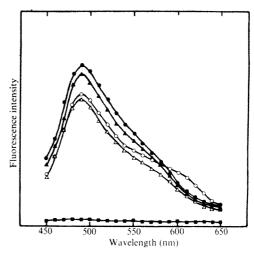

Fig. 1 Fluorescence emission spectra recorded with a Leitz microspectrograph using xenon lamp 405 nm excitation. Spectra recorded for the vacuolar region of different fluorescent cells before (●) and after (○) plasmolysis in epidermal tissue inoculated with B. cinerea and a cell from uninfected epidermis (■). Spectra of wyerone (Δ) and wyerone acid (▲) dried on to microscope slides from solution in ethanol and mounted in distilled water.

extracted from epidermal tissues it is probable that the fluorescence of live cells was largely caused by wyerone acid in the cell vacuole.

The presence of wyerone acid in live cells could result from its production by these cells or accumulation from adjacent necrotic cells and surrounding intercellular fluids. The occurrence of isolated, brightly fluorescent cells, however, rather than a zone of fluorescent tissue around necrotic sites strongly suggested that individual cells were actively synthesising the phytoalexin. The fluorescence of wyerone acid in necrotic cells may have been masked by the accumulation of ultraviolet-absorbing substances during cell browning. We conclude that wyerone acid can be produced by live cells within infected tissue.

These results raise several possibilities concerning the relationship between host cell death and the production of wyerone acid by the broad bean plant. Phytoalexin production may be triggered initially by cell death in response to fungal invasion and metabolites released from dead cells may induce subsequent biosynthesis of wyerone acid in adjacent living cells. Alternatively fungal metabolites may act as specific inducers of phytoalexin production which may be confined to live cells where wyerone acid may ultimately reach phytotoxic concentrations and cause host cell death. It is hoped that further use of the microspectrograph and detailed microscopical observations on the early stages of infection will allow these possibilities to be examined.

We thank Dr A. E. A. Porter for samples of wyerone and wyerone acid and Prof. J. S. Gillespie for use of the microspectrograph. This work was supported by the Agricultural Research Council.

### Data processing by the chemotaxis machinery of Escherichia coli

THE chemotactic behaviour of Escherichia coli provides a useful model for study of the molecular basis of a simple stimulusresponse sequence. Chemical stimuli are detected by specific receptors2 which in turn alter the rotation of the flagella3 to elicit movement towards attractants or away from repellents. About twenty types of chemoreceptors have been identified in E. coli<sup>4-6</sup>, suggesting that a communication system transmits sensory data from the receptors to the flagella, and that signals from different receptors converge either before or on reaching the flagella. I have attempted to dissect this system by isolating and examining nonchemotactic (che) mutants of the type first described in E. coli by Armstrong et al.7. In this report I summarise the properties of che mutants and derive a model of the chemotaxis machinery based on this genetic analysis.

Chemotaxis in E. coli is mediated through variations in the frequency of directional changes (tumbles) that occur during swimming8.9. When bacteria sense an increase in attractant concentration8-10, or a decrease in repellent concentration11, tumbling is suppressed, causing net migration in the desired direction. Berg and Brown<sup>8</sup> proposed that tumbles are initiated by a 'tumble generator' and that tumble frequency is controlled by chemoreceptor signals that modulate this generator. Since E. coli swim by rotating their flagellar filaments<sup>12,13</sup>. tumbling depends on the direction of rotation3. Counterclockwise rotation causes straight swimming; reversal to a clockwise direction initiates tumbling.

Chemotaxis mutants that are motile but cannot respond to any stimuli (che mutants) should define common components of the chemotaxis machinery, including the tumble generator, provided that such components are not an essential part of the flagellum or its motor. Table 1 summarises the swimming behaviour of the che mutants studied by Armstrong et al.7,14 and myself (in preparation).

All the mutants, which represent four genes, exhibit aberrant swimming patterns due to incessant tumbling or loss of tumbling. This result indicates that most or all of the common components of the chemotaxis machinery that are not essential for viability are required for generating and regulating tumbles.

Table 1 Properties of generally nonchemotactic (che) mutants

Complementa-	No. of independer	it isolates	Swimming
tion Class*	Armstrong et al.7.14	Parkinson <sup>†</sup>	pattern!
che A	16	72	No tumbling
cheB (type 1)	21	68	No tumbling
cheB (type 2)	en titologico de la constanta	26	Incessant tumbling
cheC	1	3	No tumbling
che D	Manageries -	3	No tumbling
CHE D	warmhara.	3	No tumbling

<sup>\*</sup>In the original complementation study of Armstrong and Adler14, gene assignments were made on the basis of abortive transduction tests. These assignments were confirmed† using F-prime episomes to construct stable partial diploids.

†This work is in preparation. ‡Bacteria were grown at 35° C in tryptone broth to an absorbance at 590 nm of 0.3, and were either observed directly with the light microscope or were first washed and resuspended in 10 mM potassium phosphate (pH 7) plus 0.1 mM EDTA. Swimming patterns are the same in either case.

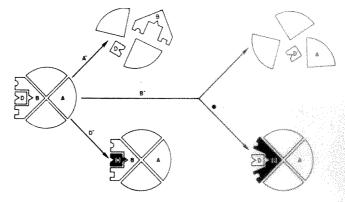

Fig. 1 A model of the tumble generator based on the properties of generally non-chemotactic (che) mutants. A further explanation is given in the text.

Although mutations in the che genes can lead to altered tumbling patterns, this does not necessarily mean that the product of each gene is required directly for tumbling. Che mutants might define not only parts of the tumble generator but also components that interact with the generator to modify tumbling behaviour. The role of each che gene product can best be inferred from mutants that lack entirely the product or function of a che gene. As the null phenotypes of the che genes reveal (Table 2), several che gene products are not involved directly in generating tumbles. The product of the cheC gene seems to be an essential component of the flagellum since Silverman and Simon<sup>15</sup> showed that in its absence the flagellum is not assembled. Motile, nonchemotactic cheC mutants cannot tumble, and must represent special alterations of the cheC product that permit assembly of a flagellum that can rotate only counter-clockwise.

The product of the cheD gene is not required for tumbling, since in its absence, tumbling is normal although chemotaxis to serine5.16 and some repellents6 is lost. But, some alterations of the cheD product do lead to a loss of tumbling ability. Since these mutants are invariably dominant (my work in preparation), it seems that an appropriately altered cheD product can interact with and inhibit the tumble generator.

Table 2 Phenotypes of null mutants in the che genes

Gene che A che B che C che D	Swimming phenotype No tumbling No tumbling Nonmotile Wild type <sup>8</sup>	Chemotaxis phenotype Generally non-chemotactic Generally non-chemotactic Non-chemotactic (no flagella) <sup>15</sup> Specifically non-chemotactic to serin	ie <sup>a, 16</sup>
che D	Wild type <sup>8</sup>	Specifically non-chemotactic to ser and to some repellents <sup>6</sup>	

Null mutants are those with a complete loss or with total inactivity of a particular gene product. The null phenotypes of the che genes were determined in various ways, most of which involve the study of nonsense or deletion mutants in these genes (my work in preparation).

Thus the normal cheD product may function as a 'switch' to control the tumble generator in response to serine signals and some repellent signals. In nonchemotactic cheD mutants this switch may be frozen in the 'off' position to prevent tumbling.

The products of the cheA and cheB genes are probably part of the tumble generator since null mutations in these genes result in a nontumbling phenotype (Table 2). The cheB product, however, seems to have a dual role which is reflected in the two tumbling patterns of cheB mutants (Table 1). The non-tumbling cheB mutants indicate that cheB product is needed to generate tumbles, and the incessantly tumbling cheB mutants indicate that cheB product also plays a part in regulating tumble frequency.

What is the nature of the defect in the incessantly tumbling (uncoordinated17) cheB mutants? On the one hand, tumbling mutants might have hyperactive tumble generators, and if this is the case, each mutant should respond equally well or poorly

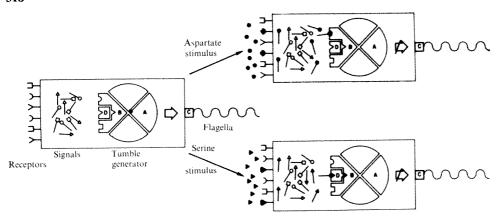

Fig. 2 The role of the tumble generator in chemotaxis. A further explanation is given in the text.

to different stimuli. On the other hand, tumbling mutants might be poorly coupled to the receptor signals that control tumbling rates, as Berg and Brown suggested. In this case, the tumbling frequency of the mutants represents not an overactive generator but rather a free running generator, unmodulated by receptor signals. If the tumble generator in these mutants is defective in its reponse to modulating signals, different signals might be perceived with different efficiencies and thereby elicit different responses.

Tumbling mutants respond to sudden changes in attractant concentration although not as well as wild type (Table 3 and refs 3 and 18). In most cases tumbling mutants do not respond with the same efficiency to the attractants aspartate and serine which are detected by different chemoreceptors. Some mutants (e13p1, e16f1, e19e1, e27f1) respond to serine but respond poorly or not at all to aspartate; other mutants (e16h1, e16n2, e17a1, e20t2, e26e2, e28h2) respond to both types of stimuli,

\*Bacteria were grown at 35° C in minimal salts-glycerol medium to an optical density at 590 nm of 0.2. The cells were washed and resuspended in 10 mM potassium phosphate (pH7) containing 0.1 mM EDTA at an optical density at 590 nm of 0.1. Samples of the bacteria were then incubated at room temperature for 15 min in the presence of 0.1 mM attractant (either aspartate or serine) before an experiment began. To minimise changes in background attractant concentrations, each set of measurements was completed within 15 min thereafter. Drops containing 20 µl of bacteria in attractant were placed on microscope slides and incubated for 1 min. The cells were then stimulated by the addition of 1 µl of attractant, bringing the final concentration to 0.3 mM (3-fold jump) or to 3 mM (30-fold jump). If the bacteria could respond, they stopped tumbling and began to swim in straight lines for a period that varied directly with the stimulus size. The times shown are subjective estimates of the time it took for 50% of the responding cells to begin tumbling once again. Differences between independent observers were not significant and the data were pooled to give the averages and standard deviations and (in parentheses) the number of measurements made. These estimates are quite accurate for tumbling mutants because the two behavioursswimming and tumbling—are very distinct and the transition time is short relative to the response time. The wild type is more difficult to measure because its normal tumble frequency is not as great as in tumbling mutants.

†Each of these tumbling mutations is in the cheB gene. All the mutant alleles were transduced into a common genetic background for these experiments. Mutants e20t2, e26e2, and e27f1 are amber (nonsense) mutants.

and one (e21e1) responds poorly to both. Comparisons between mutants (for example, e17a1 with e27f1 or e16n2 with e28h2) show that two mutants can have the same response to one stimulus but a different response to another stimulus. These results suggest that tumbling mutants cannot be modulated properly by chemoreceptor signals and that these signals control tumbling frequency by interacting with the *cheB* product.

A model of the tumble generator based on these findings is presented in Fig. 1. The generator has three components (and perhaps others not yet detected by mutation) each of which can mutate to produce a generally nonchemotactic phenotype in one or more ways. The cheC product is assumed to be a component of the flagellum rather than a part of the tumble generator itself. The products of the cheA and cheB genes are essential components of the tumble generator. Both are required to generate tumbles, but the cheB product also controls tumbling rate by interacting with signals from the chemoreceptors. The cheD product is also thought to be a component of the tumble generator although the cheD product is not required for tumbling. Rather, the cheD product is a component of the tumble control system, passing serine signals and some repellent signals to the tumble generator.

Since the cheB product is ultimately responsible for controlling tumbling rate in response to chemoreceptor signals, the model assumes that the cheD product interacts directly with the cheB component in transmitting signals to the tumble generator. This interaction can be demonstrated in three ways. First, it is possible to isolate suppressors of cheD mutants that are mutations in the cheB gene. Second, double mutants containing a cheB tumbling mutation and a cheD nontumbling mutation tumble either incessantly or not at all depending on the severity of the cheB defect as measured by temporal stimulation. Third, the response of tumbling cheB mutants to aspartate stimuli can be altered greatly by cheD null mutations, suggesting that the configuration of the cheB product can be changed by removing the cheD product from the generator. (A complete description of experiments on the interaction of the cheB and cheD products will be presented separately.)

The postulated role of the tumble generator in chemotaxis is shown in Fig. 2. The tumble generator is probably controlled in a negative manner by inhibitory signals whose level is modulated by the various chemoreceptors. In the absence of stimuli, the level of inhibitory signals is low, and consequently tumble impulses are frequently sent to the flagella. The level of inhibitory signal rises whenever stimuli are detected by the chemoreceptors; different receptors control different inhibitory signals. Aspartate signals (and presumably several others) interact directly with the *cheB* component, whereas serine signals and some repellent signals are transmitted to the tumble generator through the *cheD* product.

When E. coli are presented simultaneously with an attractant and a repellent the response depends on the relative strengths of the conflicting stimuli<sup>11,19</sup>. The model of the chemotactic process presented in Fig. 2 implies that opposing stimuli can be integrated at several points depending on the nature of the

stimuli. For example, the chemoreceptors for serine and for some repellents may control the same signal, in which case integration would take place at the signal level. If different signals are controlled by these receptors, they would be integrated at the cheD product. Other combinations of stimuli. for example, aspartate and a repellent, would be integrated by the cheB product.

These studies of chemotaxis mutants indicate that at least two types of chemoreceptor signal are transmitted to the tumble generator. Although nothing is known about these signals, it seems unlikely that they will prove to be electrical unless each signal is associated with a different class of ions. Perhaps chemoreceptors communicate with the tumble generator by mechanical or chemical means. In any event, the central role of these signals in the chemotactic process emphasizes the importance of learning more about their nature and their mode of transmission.

#### Transfection of non-host bacterial spheroplasts with bacteriophage ФX174 DNA

BACTERIOPHAGE ФX174 containing circular single-stranded DNA (SS-DNA) can infect Escherichia coli C and Shigella<sup>1-4</sup>. Progeny phages are produced through synthesis of circular double-stranded DNA (replicative form, RF-DNA) as the intermediate5,6. ΦX174 cannot infect bacteria which have no specific receptors for phage adsorption on the cell wall. The host range in  $\Phi X$  infection is thought to be determined primarily by success or failure of adsorption and if most of the cell wall is removed from the bacterium, the host range is extended and  $\Phi X$ -DNA can infect E. coli strains other than the host, and produce progeny phages. But if the recipient bacterial spheroplasts are of species distantly related to the host,

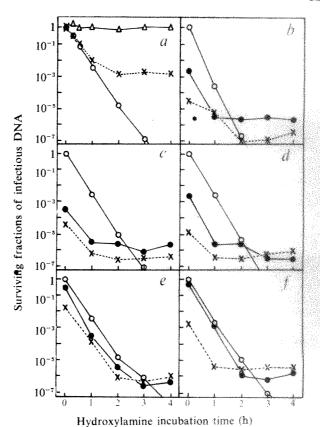

Fig. 1 Hydroxylamine treatment of the infectious materials extracted from  $\Phi X$ -SS-DNA-transfected spheroplasts. The bacterial spheroplasts ( $10^9$  cells ml<sup>-1</sup>) were incubated with SS-DNA ( $10^{12}$  molecules ml<sup>-1</sup>) for 15 min and then PAM medium was added and incubation was continued further (see legend of Table 1). At intervals, spheroplasts were lysed by the addition of 1/20 volume of 12.5% Sarkosyl NL97 and the lysates were extracted by phenol and nucleic acids were precipitated by alcohol, resuspended in 0.05 M Tris-HCl, pH 6.0, added with 1/5 volume of 1 M hydroxylamine-HCl, pH 6.0, and incubated at 37° C. At intervals, aliquots were diluted and their surviving infectivity was assayed on E. coli K12W6 spheroplast. The surviving fraction was expressed as the ratio of PFU in spheroplast assay at the indicated time of hydroxylamine treatment to PFU of the sample not treated with hydroxylamine in which SS-DNA was added to spheroplasts previously lysed with Sarkosyl and phenol. •, 15 min incubation before the addition of PAM medium; ×, 15 min incubation after the addition of PAM medium; O, SS-DNA added to the previously lysed spheroplasts. a, E. coli K12W6, Purified SS-DNA (O), RF-DNA (A) and SS-, RF-DNA mixture (×), incubated with 0.2 M hydroxyla-mine-HCl, pH 6.0, at 37° C. b, K. pneumoniae; c, S. marcescens; d, P. vulgaris; e, P. aeruginosa; f, E. coli K12W6.

ΦX-DNA may not be able to penetrate into the spheroplasts and replicate and produce progeny phages as well as in the host spheroplast. It is known that  $\Phi X$  phage replication in E. coli depends largely on host functions; for example, the ΦX-DNA replication is greatly affected by several genes responsible for host DNA synthesis<sup>7,8</sup>. On this basis, ΦX-DNA replication in bacteria distantly related to the natural host might on the one hand fail because of incompatibilities between  $\Phi X$ -DNA and bacterial gene functions or on the other hand be successful because common gene functions are widespread throughout a wide range of bacterial species. We tried to transfect OX-DNA to various bacteria belonging to the Enterobacteriaceae and Pseudomonas aeruginosa to examine the capability for phage production in bacteria other than the host, and found that ΦX-RF-DNA synthesis proceeded as efficiently as in the natural host in distantly related species of bacteria, but that progeny phage production was greatly reduced. Bacterial relationships determined on the basis of DNA homology.

Preparation of spheroplasts and transfection were performed

Table 1 Efficiency of transfection in various bacterial spheroplasts

	Effi	ciency

	SS-DNA	RF-DNA	homology10
Escherichia coli K12W6	$4.1 \times 10^{-3}$	$8.0 \times 10^{-5}$	101%
В _	$5.3 \times 10^{-4}$	$2.4 \times 10^{-6}$	100
$\widetilde{\mathbf{C}}^{\mathbf{r}\mathbf{\Phi}}$	$2.1 \times 10^{-4}$	$3.0 \times 10^{-6}$	-punctions.
Salmonella typhimurium	$2.1 \times 10^{-6}$	$2.9 \times 10^{-8}$	71
Aerobacter aerogenes	$1.4 \times 10^{-8}$	$3.5 \times 10^{-9}$	51
Klebsiella pneumoniae	$4.5 \times 10^{-8}$	$1 \times 10^{-10} >$	25
Proteus vulgaris	1.0×10 <sup>-9*</sup>	$1 \times 10^{-10} >$	14
Serratia marcescens	$2.1 \times 10^{-8}$	$1 \times 10^{-10} >$	7
Pseudomonas aeruginosa	$1.5 \times 10^{-9*}$	$1 \times 10^{-10} >$	1

Spheroplasts of all bacterial strains were prepared essentially according to the method of Guthrie and Sinsheimer. DXam3-SS-DNA (1010 molecules ml<sup>-1</sup>) in 0.05 M Tris-HCl, pH 8.1, was added to an equal volume of spheroplast stock solution in PA medium (10° spheroplasts ml<sup>-1</sup>) and incubated for 15 min at 37° C. After an addition of eight volumes of PAM medium, incubation was continued for 120 min and then the spheroplasts were lysed with chloroform and the titre of the lysates was determined. Transfection of  $\Phi$ Xam3-RF-DNA (10<sup>10</sup> molecules ml<sup>-1</sup>) was performed in the same manner as SS-DNA. The efficiency of transfection which is the average of eight experiments is expressed as plaque forming units (PFU) obtained per input  $\Phi X$ -DNA molecule. Data of DNA homology are cited from McCarthy and Bolton<sup>10</sup>

\*Values indicate averages of several experiments where plaque formation was observed.

essentially by the method of Guthrie and Sinsheimer9. The percentage of bacteria surviving after the osmotic burst treatment was less than 0.5% in all spheroplast preparations. In the transfection of E. coli K12, B and C<sup>r</sup>Φ (a ΦX-resistant mutant of E. coli C) the number of progeny phages produced was proportional to the amount of input  $\Phi X$ -DNA until saturation occurred at about 10³ ΦX-SS-DNA molecules per spheroplast. The efficiencies of transfection of  $\Phi X$ -SS-DNA and RF-DNA are shown in Table 1, together with the homology of the bacterial DNA reported by McCarthy and Bolton<sup>10</sup>.

In the case of SS-DNA transfection with Proteus vulgaris and P. aeruginosa spheroplasts, phage production was sometimes not observed, probably as a result of inefficient and variable competence in transfection. The efficiency of RF-DNA transfection was lower than that of SS-DNA transfection in E. coli K12W6 (ref. 11) and about 50 times lower than our own results with SS-DNA. For instance, progeny phages could not be found in RF-DNA transfection in Klebsiella pneumoniae, P. vulgaris, Serratia marcescens and P. aeruginosa, probably as a result of phage production at a level too low to be detected.

We therefore examined whether  $\Phi X$ -RF-DNA synthesis occurred in spheroplasts of these bacteria. To determine RF-DNA in the presence of excess input SS-DNA, DNA was extracted by phenol from spheroplasts infected with SS-DNA at intervals and treated with hydroxylamine which inactivates SS-DNA but not RF-DNA<sup>12</sup>. The amount of RF-DNA synthesised was determined from the surviving, hydroxylamineresistant infectivities in a spheroplast assay on E. coli K12W6.

Table 2 Efficiencies of RF synthesis and phage production

	Effic	ciency
Bacterium	RF equivalent per spheroplast	Phage per RF equivalent
E. coli K12W6	$2.3 \times 10^{-2}$	2.0×10
K. pneumoniae	$2.3 \times 10^{-3}$	$1.3 \times 10^{-5}$
S. marcescens	$7.7 \times 10^{-3}$	$3.2 \times 10^{-6}$
P. vulgaris	$1.0 \times 10^{-2}$	$2.4 \times 10^{-7}$
P. aeruginosa	$2.3 \times 10^{-2}$	$4.3 \times 10^{-7}$

Mean value of PFU in the spheroplast assay 3 and 4 h after the addition of hydroxylamine in Fig. 1b-f was taken as infectivity of RF-DNA. The number of RF molecules was calculated from the standard curve (not shown) of phage-yield against RF-DNA molecule in the spheroplast assay.

As shown in Fig. 1a, the infectivity of SS-DNA decreased to less than 10-7 after hydroxylamine treatment for 3 h, whereas that of RF-DNA was not affected. In all bacteria tested it was found that the infectivity surviving after hydroxylamine treatment for 4 h was almost as much as that of E. coli K12W6 (Fig. 1b-f). Decreased infectivity of input SS-DNA (see time zero of hydroxylamine treatment) was found in most bacteria tested, especially in P. vulgaris, S. marcescens and K. pneumoniae and is probably the result of the action of extracellular and intracellular DNases. Infectivity decreased as the time of incubation of DNA with spheroplast was increased. The frequency of hydroxylamine resistant infectious materials together with that of phage production is shown in Table 2. It seems that synthesis of RF-DNA (at least parental RF) proceeded to a similar degree in all bacteria, irrespective of phage production. Therefore, variable capability to produce progeny phage seems to be caused by a difference in blocking of later processes.

There seems to be some correlation between the efficiency of phage production and the order of bacterial DNA homology. This is not a simple reflection of difficulty of DNA penetration into the bacterial cell or degradation of  $\Phi X$ -DNA by DNases, if any, before and/or after penetration, since apparently there were no great differences in the extent of RF-DNA synthesis among all the bacteria tested. It has been reported that T4 phage treated with urea transfects spheroplasts of Salmonella anatum, P. vulgaris, S. marcescens and Aerobacter aerogenes with a higher efficiency of progeny phage production13 than  $\Phi X$ -DNA. The difference of efficiency between 14 and  $\Phi X$  might reflect differences in dependence of phage growth on host functions. Phage T4 has a complex genetic composition which makes it highly autonomous compared with ΦX which is less complex and needs several host gene functions even for the conversion of SS-DNA to parental RF14.15. There seem to be common factors in the machinery of RF synthesis in the bacteria tested, although the more distant is the relationship with the host, the less affinity or combatibility is there between the host functions and phage products with a concomitant reduction in phage production. The characterisation of hydroxylamine-resistant infectious material is now in progress, as is the examination of restriction as one of the possible mechanisms for a low efficiency of phage production in some bacteria.

#### Selective blockage of bacteriophage T<sub>4</sub> assembly by chemical modification

A QUESTION of fundamental importance to structural biology is the molecular nature of the contact points which direct the protein assembly process in an extraordinarily selective and efficient manner. This problem is closely parallel to other areas of biology involving macromolecular recognition, such as enzyme/substrate specificity and antigen-antibody interaction. A promising system for the study of such structural problems is the bacteriophage T4 which is a macromolecular in the process of uniting the half fibres and attaching the fibres to the otherwise complete phage particle. The basic strategy employed was to subject a defective lysate to a specific modification reaction and then see if the lysate loses the ability to donate the specified phage component, in a suitable in vitro complementation test, while the background, completely assembled particles, survive unscathed. In this way attention was focused on critical sites exposed only in the unassembled state. To further focus on those sites which may be involved in the attachment process (as opposed to, for example, interferring with the infection process), a post-activation procedure was instituted whereby it could be ascertained not only that a modified site had blocked assembly but, furthermore, that the modified component had not been assembled to form a non-infectious particle. While hoping to study the actual contact sites, we recognise that an inherent weakness of this kind of approach is the a priori inability to distinguish modification at an 'active centre' from modification at a distant site which effects the observed blockage through some sort of unspecifiable conformational mechanism.

	vitro complementation between fibre defective lysates

Treatment	Reference	pΗ	Expected target	Result
Maleic anhydride	9	7.0	Amino	Complementation reflected sensitivity of whole phage
1-fluoro-2,4-dinitrobenzene (FDNB)	10	9.0	Sulphhydryl and amino	Complementation reflected sensitivity of whole phage
N-bromosuccinimide (NBS)	11	7.0	Sulphhydryl and aromatic	Complementation reflected sensitivity of whole phage
N-ethylmaleimide (NEM)	9	7.0	Sulphhydryl and amino	Complementation reflected sensitivity of whole phage
Woodward's reagent K	12	7.0	Carboxyl	Complementation reflected sensitivity of whole phage
Rose Bengal photoxidation	13	7.8	Imidazole	Whole phage and complementation insensitive
Iodoacetate, iodopropionate, iodoacetamide	14	5.0	Thioether	Whole phage and complementation insensitive
Iodoacetamide Iodoacetate, iodopropionate, iodoacetamide	14	7.0	Sulphhydryl, imidazole, and thioether	Complementation impaired while control phage insensitive

For each reagent tested, defective lysates lacking proximal half fibres (34-:34am A 455), distal half fibres (37-:37am N91) or whole fibreless particles (23-/10-:23am H11/10am B255) were prepared as previously described 15. The standard phosphate buffer used throughout this investigation was made of 7 g Na<sub>2</sub>HPO<sub>4</sub>, 3 g KH<sub>2</sub>PO<sub>4</sub>, 4 g NaCl and 1 l H<sub>2</sub>O). After autoclaving, 10 ml of 0.1 M MgSO<sub>4</sub> was added. Before treatment, the lysates were transferred into the appropriate buffers by dialysis in the cold (4° C). The reaction was stopped and the reagent removed by exhaustive dialysis in the cold. The treatment of the control and experimental complex was identical expert for the emission of the modification. exhaustive dialysis in the cold. The treatment of the control and experimental samples was identical except for the omission of the modification reagent. Exposure to the treatment buffers did not inactivate phage or interfere with subsequent complementation. A full description of the treatments may be found in the references cited in the Table. For each treated sample the titre of background phage was measured to determine the effect of modification upon phage viability. *In vitro* complementations were carried out by mixing 25 µl of the treated 34<sup>-</sup>, 37<sup>-</sup> or 23<sup>-</sup>/10<sup>-</sup> defective lysate respectively with 25 µl of (37<sup>-</sup> or 23<sup>-</sup>/10<sup>-</sup>), (34<sup>-</sup> or 23<sup>-</sup>/10<sup>-</sup>) and (37<sup>-</sup>) and incubated for 24 h at 30° C. The mixtures were then diluted with 25 ml of the standard buffer and assayed. Each complementation test of a treated lysate was accompanied by the parallel complementation of the control.

complex built up of discrete assemblies such as head, tail and tailfibres

During the restrictive growth of conditional lethal mutants of this bacteriophage1, phage development is blocked at the step which requires the product of the mutant gene and frequently recognisable structural components accumulate. With the demonstration that many of these components are normal phage precursors which can be used in in vitro studies of virus assembly2, the way is open for direct biochemical investigation of the molecular basis of contact point specificities. From among the many described steps of phage assembly3, the junction of the half fibres and the attachment of the complete tail fibres to the base plate were chosen for closer scrutiny because the molecular composition of both fibre4 and base plate have been thoroughly examined, the contact points are topologically relatively restricted, and the reactions go well in vitro2. The process of fibre attachment seems to pass through an intermediate in which fibres (as half or whole fibres) are transiently bound to head-related 'jig' sites6-8 before final binding to the base plate.

We have investigated the use of specific amino acid modification as a probe for identifying and labelling the sites involved

Various treatments employed in this study and their qualitative outcomes are summarised in Table 1. The results suggest that the assembled phage is sensitive to modification of amino, carboxyl and aromatic side groups while neither assembled phage nor fibre contact sites are sensitive to reagents specific for the thioether or imidazole side groups. Sulphydryl carboxymethylation, however, with the alkylating reagents iodoacetate, iodopropionate and iodoacetamide manifest the requisite selectivity for the assembly process.

Post activation (Table 2) shows that the observed selective impairment of the in vitro complementation is indeed due to blockage of assembly. A series of experiments was carried out in which the experimental conditions (pH, reagent concentration, and duration of treatment) were varied. The results indicate that optimal discrimination between assembly blockage and phage survival is obtained by treating with 100 mM iodoacetate at pH 7.0 for 60 min at 25° C. That the three alkylating reagents used have identical effects, suggests that modification is not very sensitive to either the charge or size of the adduct. Neither the kinetics of modification (as measured by reduction in complementability) nor the kinetics of complementation with modified components, has been exhausively

					37-	background tit	$re = 2.2 \times 10^6$

Defective lysate preparation, modification and complementations were carried out as described in the legend for Table 1. As well as the previously described mutants, the following were used:  $(37^-/23^-/10^-:37am\ N91/23am\ H11/10am\ B255)$  in which the assembly of distal half fibres, heads and tails are blocked and  $(34^-/23^-/10^-:34am\ A455/23am\ H11/10am\ B255)$  in which assembly of proximal half fibres, head and tail is blocked. Titres are expressed as phage ml<sup>-1</sup>. The left hand portion of the Table pertains to the lysates subjected to carboxymethylation. A description of each stock is followed by the titres of the background phage in the treated and parallel untreated aliquots. Percent is a normalised measure of the behaviour of a treated sample relative to the parallel untreated control aliquot. The right hand portion of the Table deals with the complementation of the indicated (untreated) defective lysates with the modified and corresponding unmodified lysates. The results of the complementations are shown both as titres of the diluted complementation mixes and as percent, which is the normalised measure of the behaviour of the modified samples with respect to their unmodified control aliquots. For postactivation, duplicate pairs of complementations involving the modified lysates were set up. After the normal 24 h incubation period, one of the pair was titrated as described and the results were as shown in this Table. To the other of the pair, an aliquot of the corresponding unmodified lysate was added and the mix was incubated a further 24 h before titration. In each case, this post activation yielded 100% phage, indicating that the original incubation with modified components did not irreversibly use up the complementary components in producing inactive phage particles.

examined. Accordingly, we are not in a position to conclude whether or not the modification is a single hit or a multiple hit phenomenon, nor whether the blockage is absolute or simply slows the assembly process.

By a suitable choice of defective lysates subjected to modification, and selection of appropriate defective lysates for *in vitro* complementation, several different subassemblies and their respective contact and 'jig' sites may be differentiated. Table 2 gives the results of experiments which examine the sensitivity to modification of the proximal half fibre, distal half fibre and the complete fibre before attachment to the base plate of the otherwise complete phage particles. Although these experiments were repeated several times, with qualitatively identical results, the details of only one set are reported here.

The striking observation to emerge from these data is that the proximal half fibre, in the absence of other fibre components seems to be insensitive to modification, while both the distal half fibre and the whole fibre are sensitive to such treatment. As the whole fibre and the distal half fibre do not have obvious, exposed assembly contact points in common, the area on the distal half fibre, which recognises the 'distal jig site', is implicated. To explore this possibility further, modification of the half fibres was done in the presence of fibreless particles. An unambiguous interpretation of the results is impossible due to the complexity of the appropriate treatment and complementation mixtures. They are consistent, however, with the notion

that the distal half fibre, when attached to the 'distal jig site', is afforded a degree of protection against modification.

In a complementary series of experiments, the modification of fibreless particles in the presence and absence of unattached half-fibres was examined and a representative set of results is presented in Table 3. It can be seen that the fibreless particles are fairly sensitive to inactivation except that a degree of protection is afforded by the proximal half fibre. This observation suggests an interaction between the proximal half fibre and the fibreless particle, with the particle half of the recognition site being susceptible to modification by alkylating reagents. Recent work (B. E. Terzaghi and E.T., unpublished) with some new mutants (fibre attachment defective) is most readily interpreted in terms of just such a distinct 'proximal jig site' transiently occupied by the proximal half fibre.

While recognising the intrinsic limitations of modification experiments, as well as the very limited amount of quantitative (kinetic) work done, the qualitative results reported here indicate that this may be a fruitful avenue of investigation. By virtue of a differential sensitivity to alkylation at pH 7.0, we have been able to confirm the existence of a distal half fibre site which recognises an assembly 'jig', as well as identifying a site on the fibreless particle which possibly serves as a 'jig' for the proximal half fibre. Thus, a handle has been found for further characterisation of a transient but possibly important type of assembly contact point.

Defective lysate preparation, modification and complementations were carried out as described in the legend for Table 1, and the format is identical to that of Table 2. In addition to the mutants already described, (X4E: 34amB25/34am A455/35am B252/37am N52/38am B262) was used as a source of fibreless particles, free of fibre components.

#### Interaction of dGMP radical with cysteamine and promethazine as possible model of DNA repair

THE lethal action of ionising radiation or alkylating drugs is thought to involve the formation of electrophilic species (many of which are free radical in nature) which interact with essential molecules such as nucleic acid. The protective effect of the nucleophilic compound, cysteamine, has been attributed to its ability, first, to scavenge these species thereby preventing their reaction or, second, to reduce chemically the free radical lesion thereby resulting in its repair1,2. A similar mechanism has been postulated to explain the protective effect of promethazine against carbon tetrachloride-induced liver damage3,4.

Although the scavenging actions of cysteamine (RSH) and promethazine (PZ) towards several electrophilic intermediates have been observed directly4-6, their reaction with nucleic acid related free radicals has not. Furthermore, it has been generally accepted that the initial products of reaction of the electrophilic hydroxyl radical with nucleic acid bases are adducts7.8. We here report experiments which indicate that in the case of guanine derivatives, radical-cations are formed in high yield and these can react stoichiometrically with the above nucleophiles. The pulse radiolysis technique using both optical4-6 and conductometric9 analysing facilities has been employed.

On pulse radiolysis of nitrous oxide saturated solutions of either thymidine, cytidine, adenosine or guanosine  $(6 \times 10^{-4} \text{ M})$ 

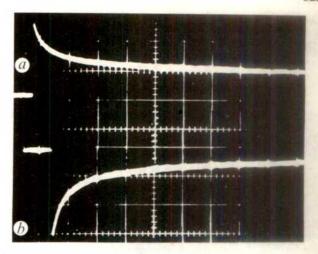

Fig. 1 Oscillograms showing changes in optical absorption and conductivity following pulse radiolysis of a nitrous oxide saturated solution of guanosine  $(6 \times 10^{-4} \text{ M}, pH = 4.6)$ . Dose about 2 k rad. a, absorption at 370 nm; b, conductivity. Time scale 1,000 µs per large division.

pH = 4-5) transient absorption spectra similar to those reported previously7,8 and attributable to the products of reactions of the hydroxyl radical, were observed. Except in the case of guanosine, little change in conductivity was observed over the same period. With the latter, a large decrease in conductivity occurred immediately after the radiation pulse. Such a change in conductivity in acid solution indicates the formation of positive ions and is attributed to the process:

$$G + OH \cdot \rightarrow G^{+} + OH^{-}$$
 (1)

where G = guanosine. The hydroxide ion is immediately neutralised:

$$OH^- + H^+ \rightarrow H_2O$$
 (2)

with the result that a highly conducting proton ( $\Lambda = 315 \Omega^{-1}$ cm<sup>2</sup>) is replaced by a less conducting cation ( $\Lambda = 50-70 \Omega^{-1}$ cm2) with a resultant decrease in conductivity. The subsequent increase in conductivity results from the liberation of a proton with the decay of the radical-cation. The optical signal at

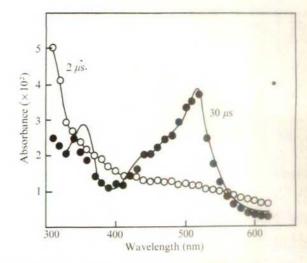

Fig. 2 Transient absorption changes observed on pulse radiolysis of nitrous oxide saturated solutions containing dGMP (10<sup>-2</sup> M) and promethazine (10<sup>-4</sup> M). ○, Experimental points taken after 2 μs; •, experimental points taken after 30 μs. The solid line through the 30 μs points is the absorption spectrum previously assigned to the promethazine hydroxyl radical adduct (see text).

370 nm measured simultaneously shows identical decay kinetics and is therefore attributed to the radical-cation (R.L.W., and K-D.A., unpublished).

In similar studies with slightly acid solutions of dGMP, radical cations were again detected. As in the case of guanosine the observable change in conductivity immediately after the radiation pulse, attributable to a reaction analogous to (1), decreased with increasing pH, no signal being observed at pH = 7. This does not, however, rule out the possibility of radical-cation formation in neutral solution. In the case of oxidised dGMP, in particular, the formation of a radical cation associated with a nitrogen atom and the simultaneous acid base dissociation of a phosphate residue would yield a zwitterion and would result in the absence of any accompanying change in conductivity. The fact that the transient optical absorption spectra of oxidised guanosine and dGMP were found to be similar in acid and neutral solution also provides support for the presence of similar species.

In the case of dGMP additional support for the formation of radical-cations is provided by studies with solutions containing excess bromide ions. Under the experimental conditions the electrophilic radicals Br2. were formed rapidly. These decayed rapidly and exponentially. The associated absorption was replaced by an absorption similar to that attributed to the radical-cation in accord with the reaction:

dGMP + Br<sub>2</sub>· 
$$\rightarrow$$
 dGMP· + + 2 Br - (3)  
 $k_3 = 4 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ 

On pulse radiolysis of nitrous oxide saturated solutions of 5' dGMP ( $10^{-2}$  M, pH = 7) and promethazine ( $25-100 \mu M$ ) the radical-cation absorption was again observed initially but decayed rapidly and was replaced by a new absorption,  $\lambda_{\text{max}} = 520 \text{ nm}$  (Fig. 2). A similar absorption at 520 nm was observed with solutions of guanosine. With thymidine, however, no such absorption was observed in agreement with the lack of formation of long-lived radical-cations on reaction of the base with OH. In the case of dGMP the rate of formation of the new absorption, which was of similar shape and magnitude to that of the radical resulting from direct interaction of the hydroxyl radical with promethazine, increased with increasing promethazine concentration according to first order kinetics.

The absolute rate constants for the reaction:

$$OH + dGMP \rightarrow dGMP + OH^{-}$$
 (4)

OH + PZ
$$\rightarrow$$
PZ (OH) · (5)  
 $k_4 = 5 \times 10^9 \text{ M}^{-1} \text{ s}^{-1} \text{ and } k_5 = 1.0 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$ 

have been measured (R.L.W., and K-D.A., unpublished and refs 10 and 11). As in the above experiment the concentration of dGMP > PZ the appearance of the 520 nm absorption must be due to reaction (4) followed by:

$$dGMP^{+} + PZ \rightarrow dGMP + PZ (OH) \cdot + H^{+} (6)$$
  
 $k_{6} = 2.8 \times 10^{9} M^{-1} s^{-1}$ 

Similarly on pulse radiolysis of solutions (pH 7.3) containing dGMP (10<sup>-2</sup> M) and cysteamine (0.2-1 mM) the exponential decay of the nucleotide radical absorption observed at 580 nm is attributed to the reaction:

$$dGMP^{+} + RSH (RS^{-}) \rightarrow dGMP + RS^{+} + H^{+}$$

$$k_{7} = 1.7 \times 10^{8} M^{-1} s^{-1}$$
(7)

These results show clearly that the direct interaction between nucleophilic agents and free radicals produced in nucleic acid can occur rapidly. As these radicals are intermediates in lesion production, the above processes constitute a 'repair' mechanism. Furthermore, although these observations have concerned the repair of lesions induced by the hydroxyl radical they could equally pertain to those induced by other electrophilic species such as those resulting from the biotransformation of carcinogenic or toxic agents, for example CCl3 ·, RNOH ·, or carbonium ions<sup>3,12</sup>.

#### Human tumours in mice confirmed by chromosomal analysis

THE growth of human tumours in mice may be evaluated by node size and histological sections<sup>1-4</sup>. Because tumour cells may fuse with host cells5-7 in vivo, it is important to ascertain which cells produce the tumour. Human chromosomes may be identified using banding procedures and this makes it possible to verify that human cells alone grow in the tumour. If chromosomal analysis is performed on the tumour before injection, it would also be possible to determine which cells were able to grow rapidly in vivo. Here we present a report on such a chromosomal analysis of a human cervical carcinoma cell line grown in immunosuppressed mice and re-established in vitro.

Human cervical carcinoma cells were cultured from primary tissue by Sykes8. For this work they were cultivated in McCoy's medium with 20% foetal calf serum. The host animals were male 4-6 week old BALB/c/CRGL mice given 400, 500, or 600 rad of whole body X irradiation followed 2-3 h later with intraveneous bone marrow cells from syngeneic donors. The mice were inoculated subcutaneously in the flank with 106 human cells in a total volume of 0.05 ml of culture medium without serum 24 h after irradiation. When a nodule was felt or when 21 d after irradiation was approaching, the animal was killed and a culture was initiated with minced tumour. Three independent tumours from mice of different irradiation doses were studied. For chromosome analysis, G bands were done with trypsin and C bands were produced using alkaline 2X SSC (ref. 9).

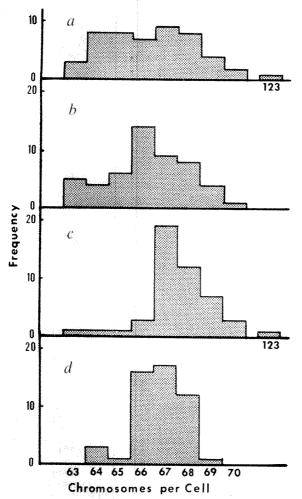

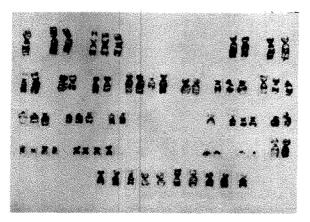

Fig. 1 Number of chromosomes counted in about 50 cells for each tumour, a, The original human cervical carcinoma cell line: b-d, cultures 1-3 (cell lines established from mousepassaged tumours taken from three separate animals).

Within 3 weeks nodules could be felt in most of the mice. These nodules measured 1  $\times$  2 mm to 4  $\times$  7 mm. Some animals were allowed to survive, with regression starting at 28-30 d after irradiation. When cultures were started at 12-21 d, the tumour cells grew well in culture.

At the time this cell line was first described, the chromosomal range of the cells was 48-130. At the time they were being grown for these experiments the cells had 63-70 chromosomes per cell with a mean of 66.1, a mode of 67 (18%), and 40% of these

Sykes tumour Giemsa-trypsin bands from a representative cell. Chromosomes were arranged according to normal and near-normal banding identification. The chromosomes on the last row showed too much rearrangement to allow positive classification.

cells having 66-68 chromosomes (Fig. 1a). After passage through mouse no. 1, culture 1 also had 63-70 chromosomes per cell with a mean of 65.6, a mode of 66 (28%) and 60% of the cells having 66-68 chromosomes (Fig. 1b). Culture 2 from mouse no. 2 had 63-70 chromosomes per cell with a mean of 67.5, a mode of 67 (38%) and 70% of the cells having 66–68 chromosomes (Fig. 1c). Culture 3 had a range of 64-69 chromosomes per cell with a mean of 66.7, a mode of 67 (34 $\frac{4}{9}$ ), and 90 $\frac{4}{9}$  of the cells having 66-68 chromosomes (Fig. 1d). The cells with 66-68 chromosomes seemingly had the capacity to grow without restraint. There were very few cells with less than 66 or more than 68 chromosomes after transplantation. Fifty cells were analysed from each tumour.

The original carcinoma line was examined by G and C bands to determine the chromosomal constitution. The majority of the chromosomes could be identified with normal or near-normal trypsin-induced banding patterns (Fig. 2). There seemed to be representatives of each human chromosome present in each cell. In cells with fewer chromosomes the A 1 was frequently absent with non-random losses from other groups. Several new arrangements were seen that could not be specifically identified as originating from particular chromosomes, but C band patterns verified that they were not mouse chromosomes. Several very small metacentrics were observed—seemingly from the fusion of 21 and 22 long arms. At least one X chromosome could be identified in most of the cells.

The three cultures examined after mouse passage did not show a marked difference in karyotypes. There did not seem to be any particular chromosomes lost or gained, although the variation from cell to cell in such a tumour makes this very difficult to ascertain. The chromosomes were all human, no mouse chromosomes were seen at all. In the three independent tumours the mean and mode of the parental line was born out as the prime growth cells.

Human tumour biopsies are frequently cultured to examine the chromosomes, do growth kinetics, and assay drug responses. There are frequently several cell types that grow from such biopsies. The animal passage of such a mixed culture can select and concentrate the tumour-producing cells as an in vivo cloning procedure. In this study, cells with 66–68 chromosomes had properties allowing unrestricted growth, and could therefore be still considered malignant. Most important, the tumour in the mouse was shown to be composed of the human cells that had been injected.

We thank Dr Joseph G. Sinkovics of the Department of Medicine, M. D. Anderson Hospital for the human tumour cell line originated by Dr John Sykes. We also thank Dr Daniel Medina of the Department of Cell Biology, Baylor College of Medicine for the gift of BALB/c/CRGL mice. This work was supported by a grant from the National Institute of General Medical Sciences to the Medical Genetics Center of The University of Texas at Houston.

#### Metabolic activation of benzo(a)pyrene proceeds by a diol-epoxide

CARCINOGENIC polycyclic hydrocarbons such as the widespread environmental contaminant, benzo(a)pyrene (Fig. 1a), undoubtedly require metabolic activitation. Boyland1 proposed that epoxides, whose formation is catalysed by the NADPH-dependent microsomal mono-oxygenases2,3, are the initial products of double-bond oxidation and we have suggested that epoxides are the important reactive metabolites responsible for the biological effects of these carcinogens4.

The properties of synthetic K-region epoxides lent some support to this hypothesis; they are alkylating agents that react covalently with nucleic acids, they are mutagenic in several systems and induce malignant transformation of rodent cells in culture<sup>5</sup>. Recent evidence suggests, however, that in cells treated with polycyclic hydrocarbons, it is not the Kregion epoxides that react with DNA6.

Here we report that in cells in culture or in model systems in vitro, benzo(a)pyrene seems to undergo a two-stage metabolic activation that initially involves the formation of the

Fig. 1 Benzo(a)pyrene (a) and 7,8-dihydro-7,8-dihydroxybenz (a) pyrene 9,10-oxide(b).

7,8-dihydrodiol<sup>7</sup>, which is then further metabolised on the isolated 9,10 double-bond by the microsomal mono-oxygenase to give 7,8-dihydro-7,8-dihydroxybenz(a)pyrene 9,10-oxide (Fig. 1b). Evidence that it is this type of diol-epoxide that actually reacts with DNA in cells treated with benzo(a)pyrene is also presented. As well as identifying, for the first time, the type of metabolite involved in the reactions of polycyclic hydrocarbons with genetic material, these findings also strongly support the general hypothesis that epoxides are ultimately responsible for the carcinogenicity of these compounds.

Primary cultures of Syrian hamster embryo cells were treated with benzo(a)pyrene labelled with either 3H or 14C. DNA was isolated from the cells, hydrolysed enzymically to nucleosides and the hydrolysates chromatographed on Sephadex LH20 columns eluted with methanol-water gradients6.8. It is already known that nucleosides are eluted in the early fractions, for example Fig. 2, peaks I, II, IV and V; Fig. 3a peaks I, II and IV and Fig. 3c peaks I and II and that polycyclic hydrocarbon-nucleoside products elute later as the concentration of methanol in the eluting solvent increases<sup>6,8</sup>. The elution profiles shown in Fig. 2 confirm that the DNAproducts formed in benzo(a)pyrene-treated cells are different from those formed in reactions of the K-region epoxide, benzo(a)pyrene 4,5-oxide, with DNA.

As there was some evidence that the further metabolism of dihydrodiol metabolites might be involved in the reactions of benzo(a)pyrene with DNA (ref. 9), 3H-labelled dihydrodiols were prepared in large-scale incubations of the radioactive hydrocarbon with rat-liver homogenate<sup>10</sup> and incubated in vitro with a rat-liver microsomal preparation and DNA11. The DNA was hydrolysed, mixed with a hydrolysate of DNA from cells treated with 14C-labelled benzo(a)pyrene and the mixtures chromatographed on Sephadex columns. Hydrolysates of DNA that had been incubated with microsomes and <sup>3</sup>H-labelled 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene gave elution profiles in which the major hydrocarbon-deoxyribonucleoside product eluted in a position similar to that occupied by the DNA product from 14C-labelled benzo(a)pyrene treated

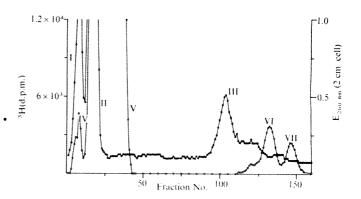

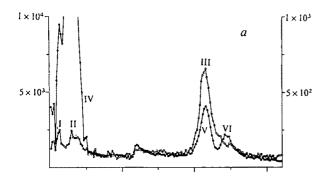

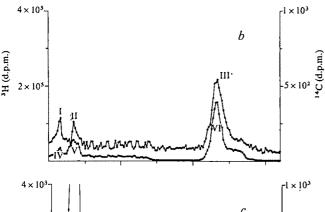

Fig. 2 Benzo(a)pyrene-deoxyribonucleoside products separated from hydrolysates of DNA by Sephadex LH20 column chromatography. •, Hamster embryo cell DNA from cells treated with <sup>3</sup>H-labelled benzo(a)pyrene; ○, DNA (salmon sperm) reacted with benzo(a)pyrene 4,5-oxide. The embryo cell DNA was obtained from primary cultures of Syrian hamster embryo cells grown in Dulbecco's MEM supplemented with foetal calf serum (15% v/v) in Thompson bottles (21) under 10% CO<sub>2</sub> in air. Confluent cell monolayers were treated for 24 h with  $^3$ H-labelled benzo(a)pyrene (1 µg ml<sup>-1</sup>) (specific activity 3.24 Ci mmol<sup>-1</sup>; the Radiochemical Centre, Amersham, UK) added as a solution in DMSO, final concentration 0.1%. Cells were collected with EDTA, the DNA isolated 15 and hydrolysed with DNase followed by phosphodiesterase and alkaline phosphatase<sup>6</sup>. Salmon sperm DNA (Type III, Sigma Chemical Co., St Louis, Mo.) (50 mg) in Tris buffer pH 7.4, 0.01 M (50 ml) was mixed with benzo(a)pyrene 4,5-oxide (2.5 mg) in ethanol (25 ml) and incubated at  $37^{\circ}$  C for 4 h. The reaction mixture was extracted with ether ( $3 \times 1$  volume), the DNA precipitated with ethanol (1 volume), washed in ethanol and ether and dried. Enzyme hydrolysates of this DNA and those of DNA from <sup>14</sup>C-benzo(a)pyrene treated cells were cochromatographed on a column (75 × 1.5 cm) of Sephadex LH20 that was eluted with a methanol-water gradient<sup>6,8</sup>. Fractions (5.3 ml) were collected and examined at 260 nm for ultraviolet absorbing materials; radioactivity was measured by liquid scintillation counting.

cells (Fig. 3a III and V). This finding was confirmed when DNA hydrolysates from embryo cells that had been treated with <sup>3</sup>H-labelled 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene were compared with hydrolysates from <sup>14</sup>C-labelled benzo(a)pyrenetreated cells (Fig. 3b, III and VI). Microsomal oxidation of the isolated 9,10-double bond present in the 7,8-diol of benzo(a) pyrene to give 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene 9,10oxide seemed likely to be the second metabolic step, especially since reactions with DNA did not occur if the dihydrodiol was incubated with microsomal preparations in the absence of the cofactors necessary for the NADPH-dependent mono-

Accordingly <sup>3</sup>H-labelled 7,8-dihydro-7,8-dihydroxybenzo(a) pyrene 9,10-oxide was synthesised and reacted with DNA and a hydrolysate compared on a Sephadex column with a hydrolysate of DNA from cells treated with 14C-labelled benzo(a) pyrene. The elution profile (Fig. 3c) obtained from DNA reacted with the diol-epoxide contained two peaks of radioactivity in the region normally occupied by hydrocarbondeoxyribonucleoside products, one of which (Fig. 3c, III) was

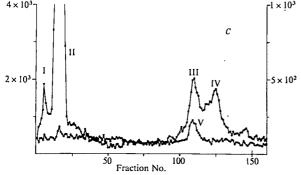

Fig. 3 Benzo(a)pyrene-deoxyribonucleoside products separated from hydrolysates of DNA by Sephadex LH20 column chromatography. a, O, DNA from hamster embryo cells treated with <sup>14</sup>C-benzo(a)pyrene (specific activity 21 mCi mmol<sup>-1</sup>). DNA was isolated and hydrolysed as described in the legend to Fig. 1.

•, DNA incubated with "H-7,8-dihydro-7,8-dihydroxybenzo" (a)pyrene in the presence of a rat liver microsomal preparation. DNA (salmon sperm) (60 mg) in Tris buffer pH 7.4, 0.01 M, (40 ml) was mixed with a washed rat liver microsomal preparation<sup>11</sup> (=5 g liver) resuspended in Tris buffer (40 ml) containing NADPH (24 mg), glucose 6-phosphate (120 mg) and glucose 6-phosphate dehydrogenase (14 units) to which <sup>3</sup>H-7,8-dihydro-7,8-dihydroxybenzo(a)pyrene (specific activity 437 mCi mmol<sup>-1</sup>) (43 µg) was added in acetone (0.2 ml). After incubation for 30 min at 37°, the microsomes were pelleted by centrifugation and the DNA reisolated and purified11. Hydrolysates of this DNA were cochromatographed with those from  $^{14}$ C-benzo(a) pyrene-treated cells. b,  $\bigcirc$ , DNA, from hamster embryo cells treated with  $^{11}$ C-benzo(a)pyrene, hydrolysed and cochromatographed with an hydrolysate of  $\bigcirc$ , DNA from hamster embryo cells treated similarly with  $^{3}$ H-7,8-dihydro-7,8-dihydroxybenzo (a)pyrene (specific activity 3.24 Ci mmol $^{-1}$ ) (0.25 µg per ml medium). c,  $\bigcirc$ , DNA from hamster embryo cells treated with  $^{14}$ C-benzo(a)pyrene hydrolysed and cochromatographed with an hydrolysate of  $\bigcirc$ , DNA reacted with  $^{3}$ H-7,8-dihydro-7,8-dihydroxybenzo(a)pyrene 9,10-oxide. The diol-epoxide was synthesised by treating the radioactive 7,8-dihydrodiol (235 µg) with m-chloroperoxybenzoic acid (200 µg) in chloroform (2 ml) at  $^{10}$ C for 48 h. After washing with NaOH and water, the chloroform solution was evaporated to dryness, the residue DNA were cochromatographed with those from <sup>14</sup>C-benzo(a) the chloroform solution was evaporated to dryness, the residue dissolved in ethanol and the epoxide purified by thin-layer chromatography on an Eastman-Kodak 6060 Chromogram developed with cyclohexane:dioxan, 1:1 (v/v). The diol-epoxide (specific activity 437 mCi mmol<sup>-1</sup>) (100 µg) in ethanol (1.5 ml) was mixed with DNA (salmon sperm) (3 mg) in Tris buffer (3 ml) and incubated, and the DNA reisolated and hydrolysed (see legend to Fig. 1).

coincident with the DNA product from <sup>14</sup>C-labelled benzo(a) pyrene-treated cells: the second product (Fig. 3c, IV) has not been further investigated. Small amounts of this second product seem to be formed when the 7,8-diol is incubated with microsomes and DNA (Fig. 3a, VI) but were not seen when either benzo(a)pyrene or the 7,8-diol were metabolised by embryo cells. The 14C- and the 3H-labelled hydrocarbon-deoxyribonucleoside products that eluted together from Sephadex columns (Fig. 3a, III and V; Fig. 3b, III and VI; Fig. 3c, III and V) were further examined on thin-layer chromatograms. Three dissimilar solvent systems failed to separate the 14C-labelled benzo(a)pyrene-deoxyribonucleoside products obtained from cells treated with the hydrocarbon from the 3H-labelled benzo(a)pyrene-deoxyribonucleoside products formed in the other experiments; in each case the 14C and the 3H-labelled products migrated together.

In other experiments, 3H-labelled samples of syntheticallyprepared 4,5- and metabolically-obtained 9,10-dihydrodiols of benzo(a)pyrene, which are also metabolites of this hydrocarbon7, were used. Hydrolysates of DNA from embryo cells treated with the 4,5- and 9,10-dihydrodiols did not appear to contain radioactive hydrocarbon-deoxyribonucleoside products although some were formed from the 9,10-derivative in microsomal incubations. Attempts to prepare 9,10-dihydro-9,10dihydroxybenzo(a)pyrene 7,8-oxide were not successful; the 9,10-double bond of benzo(a)pyrene seems to be chemically much less reactive than that in the 7,8-position.

Our results indicate that an isolated double-bond in the 9,10-position of benzo(a)pyrene leads to the metabolic formation of a 9,10-epoxide and that an epoxide formed in this position reacts effectively with cellular DNA. The dihydrodiols that are precursors of this type of epoxide are common as hydrocarbon metabolites and 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene has been detected as a benzo(a)pyrene metabolite that is formed by rodent liver and lung<sup>7,9</sup> and by human lymphocytes<sup>12</sup>. Preliminary experiments with other hydrocarbons imply that analogous metabolic activation mechanisms also apply, for example, to benz(a)anthracene and to 7-methylbenz(a)anthracene. They also indicate that diol-epoxides of the type discussed here may be effective in reaching cellular DNA simply because diol-epoxides are not good substrates either for the epoxide hydrase<sup>13</sup> or for the glutathione transferase<sup>11</sup>, enzymes that normally inactivate epoxides. The work carried out so far indicates that diol-epoxides like 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene 9,10-oxide are important in the metabolic activation of the polycyclic hydrocarbons to intermediates that react with DNA; consequently they might be expected to be biologically active and appropriate tests for carcinogenicity and mutagenicity are in progress.

#### Babesia microti and Plasmodium berghei voelii infections in nude mice

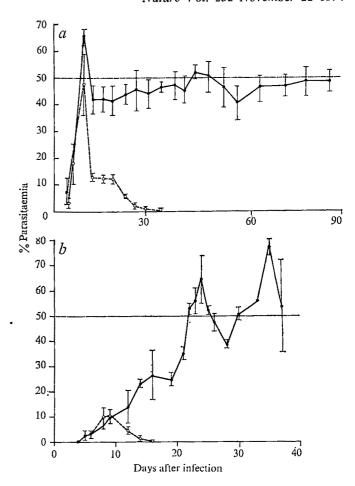

THE precise nature of the responses to Babesia spp. and Plasmodium spp. which lead to their elimination from the host and subsequent acquisition of immunity is uncertain. A degree of thymus dependence is involved, as shown by the aggravation of infection by neonatal thymectomy1,2, anti-thymocyte serum3 and anti-lymphocyte serum4.5. For instance, parasitaemias due to P. berghei were higher in neonatally thymectomised rats than in controls, and lasted about twice as long, with higher mortality1,2.

The recent availability of congenitally hypothymic (nude nu/nu) mice allows a more critical appraisal of the importance of the role of thymus competence in the elimination of these parasites. B. microti and P. berghei yoelii produce transient parasitaemias in normal mice, followed by recovery and resistance to challenge with the same species of parasite<sup>6,7</sup>. We have investigated these infections in nude mice.

Groups of three nude mice or normal littermates 6-8 weeks of age were infected by intraperitoneal inoculation with 108 erythrocytes parasitised by either B. microti (King's 67 strain, provided by Dr F. E. G. Cox) or P. berghei yoelii (17 × strain, from Dr N. Wedderburn). The nude mice were housed in germ-free isolators. Tail blood smears were stained with Giemsa, and the number of parasitised cells in 400 erythrocytes counted. The course of the B. microti infection is summarised in Fig. 1a, and of P. berghei yoelii in Fig. 1b. Means and ranges are indicated.

Following a latent period that was the same in all cases, there was a transient parasitaemia in littermate control mice and a persistent parasitaemia in nude mice. Apparent differences in the nature of this persistence of each parasite can be explained in terms of preference for different developmental stages of the red cell series, for whereas B. microti seems largely to be restricted to mature red cells P. berghei yoelii parasitises only reticulocytes. Nearly all the reticulocytes in the P. berghei yoelii infected nude mice contained parasites from day 10. Thus the rise in reticulocyte number with worsening anaemia, rather than any difference in the response of nude mice to the two organisms, is likely to be responsible for the overall parasitaemia remaining stable with one (Fig. 1a) and increasing with the other (Fig. 1b). A high and stable percentage of the susceptible red cell stage was infected by each organism until the nude mice eventually died or were killed.

In contrast to our findings, neonatally thymectomised rats took only twice as long as normal littermates to clear P. berghei from the peripheral circulation<sup>1,2</sup>. There is evidence that neonatal thymectomy in rats does not completely eliminate T lymphocytes8. Thus, in keeping with data obtained with anti-thymocyte serum3, the thymus dependence of elimination of Plasmodium spp. from rodents appears to be more complete than earlier work suggests.

a, Babesia microti infection in nude mice and normal littermates. b, Plasmodium berghei yoelii infection in nude mice and normal littermates. •, nu/nu; O, nu/+.

The results obtained with B. microti in nude mice (Fig. 1a) were similar to those found on giving anti-lymphocyte serum to hamsters before and during infection with this parasite<sup>5</sup>. This confirms an absolute dependence on the thymus for elimination of this parasite as well as P. berghei yoelii. Nude mice may be a more suitable model because they seem to survive persistent parasitaemias of B. microti more successfully than do antilymphocyte serum treated hamsters. On day 80, twice as long as any hamster survived, nude mice were apparently quite healthy after maintaining a 50% parasitaemia for the previous 70 d. In addition the problem of anti-lymphocyte serum standardisation inherent in the hamster model is eliminated.

In summary, the present data confirm that elimination of B. microti and P. berghei yoelii from the circulation of mice does not occur without thymus competence. It remains to be established whether the thymus-derived cells exert a helper effect in the production of a particular class or subclass of antibody required for parasite elimination, or form part of another mechanism of immunity. Further experiments are in progress to test these possibilities. Clearly the parasitised nude mouse could prove to be a useful model for further immunological research in this field.

#### Evidence for oligomeric IgA production by peripheral rat lymph nodes

A DISTINCTIVE characteristic of IgA is its polymorphic nature with regard to the molecular size. It occurs in secretions mostly as a dimer or tetramer<sup>1,2</sup> while serum IgA has a polydisperse weight distribution in many species<sup>1</sup>. It is mostly monomeric in human serum (7S) (ref. 3), mostly polymeric in the mouse<sup>4</sup> and in the dog<sup>5</sup>, but in both these and other species several molecular sizes occur in the blood<sup>1</sup>.

When extending studies on natural anti-hapten antibodies in the rat<sup>6</sup> we made the unexpected finding that natural anti-3-iodo-4-hydroxy-5-nitrophenylacetyl (NIP) of the thoracic duct lymph had sedimentation characteristics (9S–13S) similar to the secretory IgA antibodies that we could demonstrate in rabbit colostrum<sup>7</sup> and to the oligomeric IgA produced by mouse spleen cultures<sup>8</sup>. Natural antibody in the blood serum of the same rats sedimented like 19S IgM. This finding prompted us to study sedimentation patterns of anti-NIP antibodies in the blood and the lymph of immunised rats.

Rats were immunised with 10 µg NIP-SIII pneumococcal polysaccharide<sup>8</sup> or 500 µg of NIP chicken globulin (CG)<sup>8</sup> in complete Freund's adjuvant (CFA). As we wanted the antibody production to take place preferentially in the peripheral lymph nodes draining to the thoracic duct the antigen was injected into the hind foot pads. The rats were bled and cannulated (abdominal thoracic duct) 8–9 d after immunisation. Thoracic duct lymph samples were clarified by spinning for one hour at 50,000g. The lymph and the serum samples were titrated with NIP-T<sub>4</sub> bacteriophages as described earlier<sup>9</sup>. They were centrifuged through a continuous and linear 5–20% sucrose gradient in 12 ml tubes in rotor SW-41 Ti of a Beckman L 3–50 ultracentrifuge for 14 h (39,000 r.p.m.). A total of 25 fractions were collected and titrated with NIP-T<sub>4</sub>. Sedimentation constants (S<sub>20</sub>, w) were derived according to McEwen<sup>10</sup>.

The predominant antibody peaks of the blood serum had sedimentation constants of 19S and 7S. A minor 9S component could usually be detected (Fig. 1a). Antibodies of the thoracic duct had major 19S and 7S fractions but they also had considerable 13S and 11S fractions (Fig. 1b); 9S antibody could be seen as a distinct peak in some but not all lymph samples. We have found this phenomenon in all the 14 serum-lymph pairs studied so far.

In some experiments we incubated diluted lymph before centrifugation with rabbit anti-rat IgA. Anti-IgA is known to

displace or eliminate IgA but not IgG or IgM antibodies in the sedimentation pattern<sup>8</sup>. Data in Fig. 1 show that the 9S, 11S and 13S peaks were displaced by our anti-IgA and were thus very probably IgA.

The total IgA of several lymphs and sera was determined by the method of Mancini, Carbonara and Heremans<sup>11</sup>. We found that concentrations in the lymph fluid were 4–12 times higher than in the serum of the same animal. In the ultracentrifugation the IgA of the lymph fluids was fairly evenly distributed from the 7S to 15S fractions while the serum IgA was distributed from the 7S to 11S fractions.

The Stokes's radii of the four heaviest antibody fractions were determined by gel filtration according to Laurent and Killander<sup>12</sup>. They were calculated as means of two gel filtration runs, through a Sepharose 6B column  $(1.5 \times 79 \text{ cm})$ . Reference proteins in these runs included rat serum albumin, hyperimmune rabbit anti-DNP (IgG) and glutamate dehydrogenase. Their radii were assumed to be 35,51 and 60 Å respectively<sup>13,14</sup>. The fractions from the gel filtration were rerun in ultracentrifugation. Molecular weights (Table 1) were calculated using the  $S_{20, w}$  values and the Stokes radii in the formula

$$M = (6\pi\eta_{20, w} N a_{20, w})/(1 - \bar{\nu}\rho_{20, w})$$

in which  $\eta_{20, w}$  and  $\rho_{20, w}$  are the viscosity and density of water at 20° C, N is Avogardo's constant and a is Stokes's radius. The

partial specific volume (v) of oligomeric IgA was assumed to be 0.73 (ref. 15).

It is possible that 9S-13S IgA anti-NIP of the thoracic duct lymph mainly originates in the intestinal lymphoid tissue. For instance, plasmablasts generated in the regional lymph nodes may be transferred to the intestinal area and produce antibody there<sup>16</sup>. It was made unlikely, however, by the finding that when popliteal lymph nodes were removed from these rats and kept in organ cultures for 6 h without additional antigen they produced the same 9S-13S fractions which we found in the thoracic duct lymph. These again could be displaced by anti-IgA (Fig. 2).

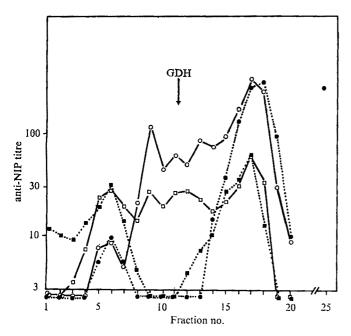

Fig. 2 Sedimentation pattern of anti-NIP activity produced by were cultured for 6 h (□, ■) or 24 h (○, ●) without additional antigen. □ and ○, untreated samples; ■ and ●, samples mixed with anti-IgA, the rat represented by open squares is represented in the same way in Fig. 1. in the same way in Fig. 1.

Data in Fig. 2 are derived from the first two lymph node cultures we tested but we have studied five nodes from five rats. Four nodes produced the 9S-13S IgA antibody. One node produced little antibody, and all of it was 19S. These data suggest that at least some 9S-13S IgA anti-NIP was produced by regional lymph nodes of our rats.

We considered the possibility that the polymerisation had taken place outside the synthesising organs. The following facts, however, fail to support it. First, individual lymph samples maintained their sedimentation pattern through weeks of storage at  $-20^{\circ}$  C. Second, centrifugation of lymph 15 min after it had left the thoracic duct showed a similar sedimentation pattern to lymph samples centrifuged later (rat no. 5 marked with closed squares in Fig. 1b). Third, in vitro synthesis of 9S-13S IgA antibody by lymph node fragments.

We believe that the different IgA antibody fractions represent different degrees of polymerisation. The molecular formulae of the three IgA fractions cannot be derived from our data but if we make the assumption that the molecular weight of the light chain, the a chain, J piece, secretory piece, and the carbohydrate content are the same in the rat IgA as those in man we find that our observed molecular weights would correspond reasonably well with the theoretical molecular weights of the following reconstructed human polymers; trimer+secretory piece+J piece (our 13S IgA), a dimer+secretory piece+J piece (our 11S IgA) and dimer+J piece (our 9S IgA).

We conclude that non-intestinal lymphoid tissues produce

polymerised IgA antibodies in immunised rats. This antibody can be demonstrated in the thoracic duct lymph and cultures of popliteal lymph nodes. It occurs in three main size classes with molecular weights of approximately 515,000, 380,000 and 280,000. In the blood these antibodies, especially the two heavier classes, are either rapidly catabolised, reduced to small subunits, or secreted.

We thank Dr Ari Helenius for his advice and help in the determination of molecular weights and Mrs Maire Laakso for the cannulation of thoracic ducts. This work was supported by the Medical Research Council, Academy of Finland.

#### Antigenic inhibition of cell-mediated cytotoxicity against tumour cells

THERE is now abundant evidence that tumour cells express new surface antigens (tumour-associated antigens, TAA)1. In many tumour models, cell-mediated immunity directed against TAA has been demonstrated in vitro2. Serum from tumour-bearing individuals has been shown to inhibit specifically cell-mediated immune responses (CMI) to the tumour target cells in vitro3, and this phenomenon may explain the paradoxical coexistence of a growing tumour and an immune response directed against the tumour. Both immune complexes of TAA with antibody4,5, and soluble TAA alone<sup>6</sup>, have been implicated as inhibitors in these sera.

In most studies, however, neither the nature of the effector cell nor the mechanism of inhibition, have been well characterised. CMI against tumours induced in mice by murine sarcoma virus (MuSV), which was measured in a microcytotoxicity assay (MCA), and in which both T and non-T effector cells were cytotoxic, was inhibited by progressor serum and by soluble TAA7, In concurrent studies with a short term 51Cr release assay, in which only T cells were cytotoxic, there was no inhibition. In antiallogeneic CMI, cytotoxicity by T cells

where I and  $I_{Inhib}$  are the % specific release by immune cells in the absence or presence of inhibitor respectively. Sera, including normal rat serum used as a control, were heat inactivated and added at a final concentration of 1:5 to lymphocytes and target cells, and to target cells alone. Irradiation was administered from a 60Co source. Anti lymphocyte globulin was made in pigs to rat thymocytes. Rats received 50 mg subcutaneously on days -4 and 0.
\*Immune cells+inhibitor/immune cells only.

could<sup>8</sup> or could not<sup>9</sup> be inhibited by soluble fractions containing H-2 antigen.

The syngeneic transplantable Gross virus-induced lymphomas (C58NT)D and W/FuG-1 are rejected after subcutaneous injection within 10-15 d in about 85% of adult W/Fu rats10. Progressive, lethal tumour growth is observed following intraperitoneal injection of (C58NT)D cells, when the tumour grows in ascitic form, or following the subcutaneous injection of either tumour in immunosuppressed rats. The CMI response of rats to these tumours, as measured in a <sup>51</sup>Cr-release assay, is mediated by T cells<sup>10-12</sup>. Here we report the inhibition of cytotoxicity by progressor sera and also by cell-free TAA.

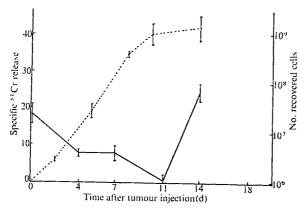

Fig. 1 Effect of progressor serum on CMI. Sera taken at various times from a group of six rats injected with 10<sup>6</sup> (C58NT)D cells intraperitoneally, were tested at a dilution of 1:5, for inhibition of CMI with 10 d immune spleen cells and <sup>51</sup>Cr-labelled W/FuG-1 cells (cell ratio 100:1). All other experimental conditions were as described in Table 1.—, % specific stor release; ---, No. recovered cells. Standard errors are indicated.

All inhibitors were tested in a 4.5 h 51Cr release assay using immune spleen cells taken 10 d following the subcutaneously injection of 108 (C58NT)D cells into adult inbred W/Fu rats10,13.

In these experiments progressive growth of tumours was obtained following the subcutaneous injection of 108 W/FuG-1 cells into immunosuppressed rats, and occasionally in normal rats. Tumour diameters were measured regularly to define the progressive and regressive phases of growth.

In Table 1, hyperimmune serum (raised by multiple injection of 107 W/FuG-1 lymphoma cells) is compared with progressor and regressor sera from the five adult rats, out of an injected group of 31, which showed tumour growth beyond 20 d. Progressor sera were taken during the phase of progressive growth between 20 and 30 d and regressor sera were taken from the same rats during regression of the tumours. Progressor sera from immunosuppressed rats were taken at 14-20 d or just before death.

Table 2 Inhibition of CMI by TAA

MuLV-G formal‡ p31		31 47		19	11	9

Immune spleen cells (5×106) were incubated with antigens for the duration of the assay. The antigens were added in 0.1 ml volumes and were also tested on target cells only. As a control, an equivalent volume of PBS was added to both lymphocytes and target cells, and to target cells only. The Gross and Moloney pseudo-types of murine leukaemia virus, MuLV (MuLV-G and MuLV-M) were purified by differential centrifugation from in vitro culture supernatants of W/Fu Gross and Moloney virus-induced lymphomas. MuSV-M was obtained from cultures of a BALB/c mouse sarcoma line (MSC)<sup>17</sup>. p31 was prepared from MuSV-M by an isoelectric focusing method<sup>18</sup>. Crude soluble extracts were made of (C58NT)D cells and normal rat spleen cells by papain digestion<sup>19</sup>. All reagents were dialysed exhaustively against phosphate buffered saline (PBS) before The results are the means of several experiments. All reagents in Tables 2 and 3 were tested at least twice and mostly three to four times. In no case was the standard error of the mean % inhibition greater than 5%. The mean of the % specific cytotoxicity, without added inhibitors, in these experiments was  $28\pm3\%$  s.e. Antigen concentrations were calculated by the method of Lowry<sup>23</sup> using bovine serum albumin as standard.

\*Crude soluble fraction of a papain digest.

†Eight freeze-thaw cycles. ‡Formalised virus, 0.01% formalin, 4° C for 2 weeks (ref. 20).

Statistically significant ( $P \le 0.01$ ) inhibition of CMI is seen with all progressor sera by comparison with regressor sera. Normal rat serum itself exerts an apparent small inhibitory effect, largely due to the lower spontaneous release of 51Cr in the presence of rat serum. When sera were tested at dilutions up to 1:10,000, augmentation of CMI was observed with hyperimmune and regressor sera, but not with progressor sera. The augmentation may reflect cytotoxicity by non-immune cells in the presence of an antibody in hyperimmune and regressor sera (lymphocyte dependent antibody)14 which, characteristically, is effective at high dilution<sup>15</sup>. The inhibitory effect of progressor sera was lost at dilutions greater than 1:20. Where sequential bleeds were taken during progression or regression of the tumour, the % inhibition of CMI was directly related to tumour diameter.

In Fig. 1, sera from adult rats with a progressive ascites lymphoma (106 (C58NT)D cells injected intraperitoneally) were tested for inhibition of cytoxicity at various times during tumour growth. The rats died at a mean of 14.7 d. Tumour growth was measured by the number of cells recovered from the peritoneal cavity. Increasing inhibition of CMI by serum

on days 4, 7 and 11 ( $P \le 0.01$ ) is seen during the tumour growth, but inhibition is lost just before death when tumour growth rate has decreased. The characterisation of the inhibitor in serum is in progress.

To test the effect of cell-free antigen alone on CMI, whole virus, the major viral group specific antigen p31 (ref. 16), and a soluble papain digest of tumour membrane, were used.

The results (Table 2) show that equal amounts of both the Gross and Moloney pseudotypes of MuLV, and formalintreated non-infectious MuLV-G, produce approximately the same inhibition of CMI. The inhibition by formalin-inactivated virus suggests that inhibition does not result from viral infection of effector lymphocytes. The group specific inhibition by virus may reflect a degree of particle disruption during virus purification with release of the internal group-specific antigens. The most abundant of these, p31, has been detected in virus stocks (R.A.K., unpublished). Furthermore, an aliquot of MuLV-G intentionally disrupted by eight freeze-thaw cycles is 2.3 times as potent as the same undisrupted virus stock (89% against 39% inhibition—Table 2). Purified p31 itself inhibits cytotoxicity.

Tabl	e 3	Specificity of inhibition		
a CMI to (C58NT)D* Antigen	ı	% Inhibition of specific dose of antigen (μ 1000 400 100 30 10	g)	is 1

\*CMI performed with 5×106 lymphocytes (that is, ratio of 100:1). †Normal or immune spleen cells from W/Fu rats immunised 7 d previously with  $2\times10^8$  murine L5178Y lymphoma cells intraperitoneally, were assayed with  $5\times10^4$  <sup>51</sup>Cr-labelled L5178Y cells for 8 h at 37° C with rocking. The results of a single typical experiment are

T lymphocytes, purified from L5178Y immune rat spleen cells by nylon column fractionation, are cytotoxic for <sup>51</sup>Cr-labelled L5178Y lymphoma cells. At a ratio of 100:1 the specific cytotoxicity of fractionated cells was 12.7%, and that of the unfractionated cells was 7.1%, in a typical experiment.

The inhibition by virus and viral antigens is specific (Table 3a). It can be seen that an antigenically unrelated virus, Newcastle Disease Virus, and soluble antigens from normal rat spleen cells do not inhibit CMI in comparison with MuLV-G. A syngeneic CMI response in the rat directed against TAA induced by an unrelated virus and measured in a short term 51Cr release assay, would have been the ideal control for the specificity of inhibition of CMI. In the absence of such a system, MuLV-G, MuSV-M and (C58NT)D extract were tested in an anti-xenogeneic system (Table 3b). The spleen cells of rats immunised intraperitoneally with  $2 \times 10^8$  murine L5178Y lymphoma cells 7 d previously, exhibit marked CMI towards 51Cr-labelled L5178Y cells in an 8 h assay, but this response was not inhibited by the added TAA.

Preliminary experiments suggest that the inhibition of CMI by cell-free TAA is at the level of the effector cell. The cytotoxicity of spleen cells was inhibited by 30% following preincubation with MuSV-M before assay (100 µg per  $5 \times 10^6$  cells). Preincubation of target cells with antigen did not alter the cytotoxicity.

These experiments were performed with unfractionated

Ì

immune spleen cells, in which T cells have been shown to be the effector cells<sup>10-12</sup>. To substantiate the direct inhibition of T effector cells by antigen, B cells and macrophages were removed by incubation of immune spleen cells on nylon wool columns<sup>21</sup>. Phagocytic cells are regularly reduced from 7-9% of total cells to about 0.5% by this procedure10. The specific cytotoxicity by column purified cells at a ratio of 100:1 (in which the percentage of immunoglobulin bearing cells had been reduced from 40% to 4%) was 35%, and was inhibited by MuSV-M virus disrupted by freeze-thawing (40 µg produced 35% specific inhibition), and by a papain digest of (C58NT)D lymphoma cells (350 µg inhibited 96%). The same spleen cell population, tested without fractionation, was also inhibited by the same dose of these antigens.

Our evidence indicates that effector T cells can be inhibited in a 51Cr release assay by progressor sera and by cell-free TAA. This differs from results obtained in the MuSV tumour model in mice where CMI was inhibited by TAA and progressor serum only in MCA, in which both T and non-T cells were cytotoxic7, and not in a 51Cr release assay. This may reflect species differences in functional accessibility of receptors to the antigens studied. Our results indicate that the expression of a cell-mediated immune response can be inhibited by antigen at the level of the final effector cell. A recent report<sup>22</sup> indicates that antigen can also inhibit the release of antibody from antibody forming cells.

Success for the competitive yachtsman must in some part depend upon the quality and reliability of the equipment he uses. Likewise for you, the researcher, these virtues must apply to your reagents for them to contribute to your success. To broaden your Biochemical Research 'horizon' Boehringer Mannheim offer the following new preparations. Reverse transcriptase (AMV) Cat.No. 15644 Adenosine-5'-0-(3-thiotriphosphate) Cat.No. 15623 (RNA-dependent DNA-polymerase) (ATP-Y-S) Purified by chromatography on DEAE-cellulose, phosphocellulose and Sephadex<sup>R</sup>G-100. Supplied at -20°C in 50% glycerol, 1mM dithiothreitol and 0.3M potassium phosphate; The latest in a line of nucleotide analogues of particular interest to anybody working on ATP-dependent enzyme systems. Supplied as tetralithium salt to facilitate solubilisation combined pH approx. 8.0. Stabilised with bovine serum with stability. Typical analysis: ATP-γ-S Li4 85%, H<sub>2</sub>O 15%. albumin (0.5mg/ml).
With oligo-dT stimulated AMV-RNA the enzyme Application: Inhibition of phosphatases and ATPases; investigation of muscle myosin; 'affinity labelling' of preparation performs well. 2'-0-Succinyl-A-3:5-MP Cat.No.15663 proteins; labelling of ATP+S binding enzymes prior to X-ray Introduced to satisfy the growing demand for an ultra-sensitive radio-immuno assay for A-3:5MP\*. Techniques currently being developed make it structural analysis or electron microscopy (ATP-Y-S has an affinity possible to measure A-3;5-MP in the p-gram range with antibodies produced from Succinylfor mercury compounds).
References: Nachr. Chern. Techn. 20, 494 (1972) A-3:5-MP linked to albumin.

Of particular interest to food analysts, and researchers and research clinical. When elucidating the type and arrangement of membrane phospholipid structures in erythrocytes the enzyme from B, cereus has the protesses, hydrolases neuraminidase and has negligible hasmolytic activity. rence: J.SHILOACH et al., Biotechnol and Bigengen XV, 551 (1973)

# PROGRESS IN IMMUNOLOGY I

Proceedings of the Second International Congress of Immunology, Brighton, United Kingdom, July 21-27, 1974.

edited by LESLIE BRENT and JOHN HOLBOROW.

# We promised it. We've done it. Breaking records all the way!

We promised to produce the giant proceedings of the Second International Congress of Immunology four months after the meeting itself

**We've kept our word.** This major five-volume work with over 2050 printed pages is published now, and it provides a permanent record of the papers given at this significant gathering of over 4000 scientists.

We couldn't have done it alone. So we'd like to thank congress speakers for submitting their manuscripts in a form suitable for camera-ready production, and workshop chairmen for producing reports within three days of the congress. And a special thank you to the stalwart team of editors and assistants who set to work preparing, editing, and indexing 123 symposium contributions and 152 workshop reports. Thank you all for your help!

Despatch of prepaid orders placed during the congress is now in hand and we hope to have copies on customers' desks before Christmas.

Biological and medical texts under the North-Holland imprint are published by ASP Biological and Medical Press, which is also responsible for the lifescience publications of Elsevier and for the primary publications of Excerpta Medica. The company produces some 60 book titles a year, including classical reference works, laboratory manuals, and advanced research level monographs; and nearly 30 journals, such as the renowned Biochimica et Biophysica Acta and FEBS Letters. Write to the address below for a computer request card, which will enable your interest profile to be matched against this publication list so that you are kept informed of forthcoming titles in your special fields.

For further copies, place your order through your bookseller or write to:

Orders placed for the set of 5 volumes will be supplied at the special price of US \$ 105.95/Dfl. 275 per set. ISBN 0-7204-7033-1

#### Volume 1: Immunochemical Aspects

1974 xvi + 328 pages. Price: US \$ 20.50/ Dfl. 53. ISBN 0-7204-7034-X.

Contents: Structure of immunoglobulins; Conformation of immunoglobulins and the effect of antigen; Biosynthesis and secretion of immunoglobulins; Complement; Workshop reports.

#### Volume 2: Biological Aspects I

1974 xii + 434 pages. Price US \$ 26.50/ Dfl. 69. ISBN 0-7204-7035-8.

Contents: The nature of antigenecity; Cyclic AMP and other intracellular mediators of cell activation; Control of the immune response; Genetic control of the immune response; Evolution of antigen recognition systems; Workshop reports.

#### Volume 3: Biological Aspects II

1974 xii + 418 pages. Price: US \$ 25.50/ Dfl. 66. ISBN 0-7204-7036-6.

Contents: Relation between structure and function of lymphoid tissue; Cell cooperation - mechanism of the immune response; Delayed hypersensitivity; Mechanisms of immunological unresponsiveness; Tumour immunology; Workshop reports.

#### Volume 4: Clinical Aspects I

1974 xii + 392 pages. Price: US \$ 24.75/ Dfl. 64. ISBN 0-7204-7037-4.

Contents: Anaphylactic hypersensitivity; Specific and non-specific immunity in infection; Immunopathology of infectious diseases; Immunological aspects of respiratory disease; Workshop reports.

#### Volume 5: Clinical Aspects II

1974 xii + 412 pages. Price: US \$ 24.95/ Dfl. 65. ISBN 0-7204-7038-2.

Contents: Autoimmunity in disease; Immune complexes and disease; Transplantation; Immunodeficiency disease; Immunosuppressive therapy; Workshop reports.

# reviews

The Interrelationships of Fishes is a very welcome volume, for it contains an up to date statement of position by leading authorities on nearly every major group of fishes and, therefore, it provides an almost comprehensive survey of the state of palaeoichthyology in 1972. Tipping the scales at three and a half pounds it is in every sense a heavyweight volume, but its publishers and editors are to be congratulated on an attractive format and a text that is almost free of blemishes.

The interrelationships of most of the groups of fish have long been uncertain. That is partly because most major groups appear suddenly, already fully distinct, in the Devonian, and partly because of the rapid and complex evolution that characterised the emergence and early evolution of the teleosts. Though some new discoveries, and even more new opinions, have appeared in the last few years, it has been difficult for the non-ichthyologist to gauge the extent to which these have been accepted, especially in their implications for the major dichotomies in the evolution of fishes.

'Dichotomies' is the obligatory term, for the procedures of phyletic analysis advocated by Hennig have penetrated more thoroughly into the world of palaeoichthyologists than into other fields of vertebrate palaeontology, and the book is notable for its uniformity of approach in such matters. Irrespective of the merits or demerits of these methods, the uniformity does make it easier to analyse the precise points at issue where opinions differ.

This well produced and carefully edited book accurately reflects current American practice in the development of hormone radioimmunoassays. Each hormone, or group of hormones, is dealt Methods of Hormone Radioimmunowith separately, with particular emphasis being given to the particular Behrman. Pp. xxi+520. (Academic: methodological problems likely to be New York and London, May 1974.) encountered. Thus the book makes an ideal companion to previous publications concerned with the practicalities field and individual chapters deal with Some chapters, such as that relating of radioimmunoassay, which consider hapten radioimmunoassays for the in- to the radioimmunoassay of ACTH, the subject under such general sections tracellular messengers (cyclic AMP as, for example, radioiodation, separa- and cyclic GMP), for three of the mation which would be easy to reprotion and antibody production. It is prostaglandins, for the adrenal and unfortunate, therefore, that the exces- gonadal steroids and for the thyroid sive price of the book will limit its pur- hormones. Other chapters relate to book is that the authors have summarchase, other than by large specialised the assay of human placental lactogen, ised the assay kits and reagents availcentres.

more, authorities in the appropriate hypothalmic releasing hormones (TRH obtained.

# Fish families

#### **Barry Cox**

Interrelationships of Fishes. Edited by P. H. Greenwood, R. S. Miles, and Colin Patterson. (Supplement No. 1 to the Zoological Journal of the Linnean Society.) Pp. xiv+536. (Academic: London and New York, January 1974; Published for the Linnean Society.) £11.00; \$31.00.

Some of the papers in this volume contain radically new views resulting from new information. For example, the increased knowledge of the onychodont crossopterygians leads Andrews to question whether the coelacanth is isolated from all other crossopterygians. She suggests instead that the primary division of the group is an osteolepid-rhizodont-onychodont assemblage and a coelacanthporolepid assemblage. By way of contrast, Bjerring considers that the coelacanths do not share any signifificant specialisations with any other group of fishes and that their origin is remote from that of the other groups.

Other new discoveries from the Carboniferous of North America, described by Zangerl, have transformed theories of the phylogeny of the chondrichthyes. There was clearly already a considerable diversity of elasmobranchs in the Carboniferous

the bizarre iniopterygians Period: show both chimaeroid and elasmobranch characteristics, and the simple view that the two groups are members of a monophyletic chondrichthyan group is again in the ascendant.

New information on the early, Upper Devonian, actinopterygians is used to substantiate current views on the interrelationships of the Actinopterygii, Crossopterygii, Dipnoi and Acanthodii. The relationships of the Acanthodii, as evidenced by the exoskeleton of the head, is also discussed in a succinct and cogent paper which concludes that they are more closely related to osteichthyans than to chondrichthyans.

Many papers involve the use of from morphological information already known groups, using Hennig's methods, to ascertain the most likely scheme of relationships. In varying degrees of details, these methods are used for the chondrosteans, the holosteans (which are found to be a paraphyletic group, and discarded), the osteoglossomorph teleosts, the clupeomorphs, the elopomorphs, the ostariophysans and the higher euteleosts. Finally, there is a new classification of living elasmobranchs, including all the different genera, and the interrelationships of the four defined superorders are dis-

The addition of a citation index and a subject index add greatly to the utility of the volume, which is a worthy tribute to Professors Stensïo and Jarvik, in whose honour the 1972 symposium was held.

# No enemy but winter and rough weather

#### Television Review by Allan Piper

On Wednesday evening, immediately following The Frost Interview, the BBC broadcast its much heralded, prestige extravaganza The Weather Machine (BBC2, November 20, 9.00 p.m.); the latest in a series of annual productions which began so successfully back in 1970 with Violent Universe. Excellently assisted by the studio commentary of Magnus Magnusson, the modulated narrative tones of Eric Porter and, more importantly, by the availability of a six figure budget, producer Alec Nisbett endeavoured to squeeze into 120 minutes of airspace the fruits of twelve months globetrotting.

The programme followed much the same format as its predecessors, with periods of studio commentary (which saw Magnusson perched uncomfortably atop a large model world looking as though he might indulge in some involuntary globetrotting himself) followed by long snippets of film. All in all, very similar to the university lectures I remember. The similarity was probably intentional and, considering the objectives of the programme, was a good idea.

The Weather Machine, like its predecessors, was scripted by Nigel Calder. But even though his undeniable competence always shone through (he was winner of the UNESCO prize for the popularisation of science in 1972) my sense of enlightenment was somewhat tempered by the banjaxed mood in which I found myself once it was all over. The production set itself too many goals; it is simply not possible for anyone comprehensively to cover so much ground in so short a time. We saw ice sheets in Greenland and tornados in America and buoys in the Pacific and some floods in Japan and a mountain in Hawaii and Magnus Magnusson orbiting Venus.

And out of it all we learned that it is getting colder and that ice sheets can form far more rapidly than was ever before realised. The long hot summer's days of the 1920s are gone for at least a few thousand years. Just around the corner are days like those remembered by Shakespeare, "when milk came frozen home in pail". Regular readers of Nature will already be aware of the more tragic consequences of that and the other climatic changes which are already becoming evident.

Given the topicality of the subject and the tremendous opportunity that it offered for some spectacular camera work the production was always just a little disappointing. Technically, of course, it came up to the usual excellent standard achieved by the BBC but in every other respect it was really rather dull television; those with black and white sets missed very little.

The production team could claim that spectacular entertainment was not their main objective in a programme which set out primarily to inform. That would be a fair argument but it is worth considering whether the programme fulfilled any requirements that had not been met already by other programmes; particularly so in view of the gigantic financial investment. Perhaps it is unfair to compare this production with Horizon, but the comparison is inevitable and, I believe, quite valid. Generally speaking, both series deal with the popularisation of serious science; several steps up from the antics of Patrick Moore and the boffinry of Raymond Baxter. And both attempt to keep the public abreast of recent advances in important areas of research.

Three Horizon programmes could have covered the same ground more effectively and perhaps more concisely. Quite definitely more cheaply. Hubert Lamb (who, as irrepressible as ever, made a brief appearance) and others like him will doubtless take that last point. How much better could those research workers have used the financial balance.

The Weather Machine had no inherent superiority over its more quotidian counterpart, only an ascribed importance supported by a cover picture in Radio Times. Although it was a brave attempt to present a comprehensive summary of the present state of a very wide field of research, perhaps the production should have gone out in two separate screenings. The real weather machine may well be changing gear; but in the present form a programme such as this can never really shift into top.

#### Book Review by John Gribbin

This is not at all a bad book. It covers a wide area, drawing on many disciplines, clearly, with lavish illustrations and at a very reasonable price. Even so, after reading it I was left with a slight feeling of disappointment because The Weather Machine does not quite live up to the standards of some of its predecessors (notably Violent Universe and Restless Earth) and it could have been better.

In spite of this, however, the book could well reach a wider audience than any of its predecessors. Climatic change, whether it 'merely' produces droughts in sub-tropical regions or leads to a full scale ice age, is rapidly becoming recognised as one of the key problems faced by mankind today. Changes in the weather are felt by

everyone, and they concern everyone in a way that advances in astronomical ideas or a better understanding of the causes of earthquakes can never do. Yet, because of the short time which has elapsed since it was realised just how quickly the climate can change, there are very few books which deal with the problem, although library shelves are laden with books on black holes, radio astronomy, earthquakes and continental drift written at all levels from the most popular to the most erudite.

When we turn to climatic change (as distinct from the weather and meteorology) I can think of only two books of broad interest that I would recommend: Hubert Lamb's Climate: Present, Past and Future (for the more academic market), and E. Le Roy Ladurie's Times of Feast, Times of Famine at a more popular level. Both are expensive, and neither provides a suitable starting point for the general reader who is concerned about what is happening to the weather.

So—partly by default—Nigel Calder's latest book is clearly the best introduction yet available to a concerned reader. As such, it will also prove invaluable to those studying these problems, although they will not all go along with the author in his firm support for the idea that ice ages are caused by the wobble of the Earth in its motion through space (the Milankovitch hypothesis). And no doubt hard core meteorologists will be interested in this concise summary of the longer view.

Perhaps the book could have gone a little further in presenting a balanced view rather than a picture of imminent climatic doom. Too much crying of "wolf" will do no good for the cause of the serious student of climatic change, and could indeed do harm. The reader is advised to take some of the extrapolations with a pinch of salt; but that is my only major criticism of what is, nevertheless, a worthwhile book.

There is still an obvious need for a more 'solid' book, as opposed to the coffee-table variety, to bridge the gap in the market between The Weather Machine and Lamb's epic-but until such a book appears this one will do to be going on with. As with most books one can quibble about points of presentation and style, but when the book has no competitors such criticism seems carping. One point, however: I would have liked to see the word 'climate' in the title; this is not really a book about weather, and the sub-title and The Threat of Ice gives, almost as a throwaway, a better impression of its theme.

The Weather Machine and The Threat of Ice. By Nigel Calder. Pp. 143. (BBC: London, November 1974.) £3.25.

# Purposeful drift of electrons

The Diffusion and Drift of Electrons in Gases. By L. G. H. Huxley and R. W. Crompton. Pp. xxiv+669. (Wiley Series in Plasma Physics.) (Wiley: New York and London, March 1974.) £19.60.

THE volume discusses the diffusion and drift of electrons in gases and little else. Dwelling only momentarily on any topics that may fringe the main theme. it concentrates without distraction on the high precision measurement of diffusion parameters and drift velocities primarily under low E/p conditions. Thus, for example, scant attention is afforded to transport phenomena under near breakdown conditions: the briefest of consideration is given to the Townsend coefficient; and ionisation and attachment are discussed with only moderate zeal. Indeed, the purpose of the measurements described is largely to provide an indirect and alternative technique for investigating low energy electron collision cross sections, yet even this topic is granted but one chapter at the end of the book and a more detailed and satisfactory account can be found elsewhere. In short then, this book is a powerful treatise on a very narrow subject.

The authors divide the book into two distinct parts dealing with theory and experiment separately. Most of the theory is developed from the Maxwell-Boltzmann equation and is concerned with the precise description of electron motion when a relatively small and constant electric field is present. Chapters are, however, devoted to high frequency fields and mixed electric and magnetic fields. A solitary chapter describing the alternative "free path" approach to the subject is a welcome addition to the section. The theory is developed rationally and the explanatory text is quite lucid. Thus, although the mathematical basis of this section may seem formidable to those not inclined in that direction (and most will find it a little tedious). it is an inevitable feature of the subject, and a more thorough or comprehensible alternative is probably not avail-

The experimental section is mainly devoted to the techniques used to measure the basic transport parameters and these are discussed at considerable—perhaps too great—length. Though in precision measurements the experimental detail often distinguishes between success and failure, no reasonable researcher will embark on a new project without having consulted the original publications. In a review—as this book is best described—it is adequate and probably advantageous to

be a little less meticulous. Nevertheless, the value and clarity of the account presented is beyond dispute. Rather inconspicuous chapters concerning the application of transport data to cross-section investigations and measurements of other, less fundamental, transport parameters conclude the section.

The book begins with an interesting historical introduction to the subject as a whole and ends with a useful summary of experimental data on the transport parameters and cross sections for a selected variety of gases. It is reasonably well referenced throughout. About one quarter of the references refer to original publications of the authors. The book will be unquestionably of value to those few with a direct interest in the subject.

R. M. Bull

An unstifled sneeze neatly captured, if not in a handkerchief, at least by high speed flash-illumination photography. From Biology: third edition. By John W. Kimball. Pp. xxiii+898. (Addison-Wesley: London, June 1974.) £5.35.

### Plants and pathogens

Genetics of Host-Parasite Interaction. By P. R. Day. Pp. xii+238. (Freeman: San Francisco and Reading, 1974.) £4.50.

In the first two editions of their book Fungal Genetics J. R. S. Fincham and P. R. Day included a chapter on the genetics of pathogenicity; they omitted it from the third edition (1973) stating that the subject had become too extensive for adequate treatment in a single chapter. Dr Day has now remedied this omission with a book which includes both hosts and pathogens.

Chapter 1 provides a short introduction to the subject. In the remainder of the book theoretical arguments and practical results are brought together to provide a comprehensive review of recent developments in ideas on the genetics of resistance (chapter 2) and pathogenicity (chapter 3), the gene-forgene concept (chapter 4), gene function in the host-parasite relationship (chapter 5), the genetical consequences of methods of disease control (chapter

6) and genetical aspects of parasite epidemics (chapter 7). The author describes his approach as speculative and at many points throughout the text gives alternative implications of theories and interpretations of results. These are always interesting and add greatly to the value of the book. The majority of examples are drawn from work on fungi but it is most useful to have many relevant references to work on other organisms. This is particularly the case in chapter 6 on biological and chemical control of plant disease where more experience has been obtained with insects than with other organisms.

The book contains over 600 references, mainly of recent origin: a most useful feature of the bibliography is that, after each reference, the numbers of the pages on which the work is quoted are given.

Use of the speculative approach makes chapter 5, on gene action, especially stimulating. In this rapidly developing area the contribution which genetic studies and the use of genetically controlled experimental material can make in helping to disentangle mere correlations from the true causes of disease resistance is emphasised. Theoretical models of gene action are described and their value in suggesting critical areas for study is illustrated. Similar value is attributed, in later chapters, to the production of computer programs for analysis of gene-forgene relationships, permitting the assignation of genes for resistance to related groups which can then be studied more intensively with conventional methods; it is also suggested that computer simulation of disease epidemics can help to identify factors for which insufficient data are available from practical investigations.

Similarities in the problems caused by genetic variability, common to attempts to control many parasites, are clearly demonstrated. In some cases, however, the application of a method of disease control may have consequences which are not confined solely to direct effects on genetic variability of the parasite. One might, for example, argue that, although destruction of barberry plants in North America did not, as Dr Day says in chapter 3, eliminate genetic variation in Puccinia graminis, it affected the overwintering behaviour of the pathogen, necessitating annual movements of spores between north and south, delaying the arrival of inoculum to northern areas in spring and changing genetic aspects of the epidemic; a fitting example for chapter 7 perhaps.

The book will appeal to advanced students and their teachers as well as to research workers and I welcome it as a timely and concise addition to the literature.

R. Johnson

# Advancing igneous petrology

The Alkaline Rocks. Edited by H. Sorensen. Pp. xii+622. (Wiley: London and New York, March 1974.) £20.00.

In this book Professor Henning Sørensen brings together contributions covering recent intensive investigations of the mineralogy, geochemistry and experimental behaviour of alkaline rocks, together with new information on their occurrence and field relations. The cover is wide but, deliberately, no attempt has been made to be comprehensive in terms of occurrence. Recently reviewed rock types (such as carbonatites) receive limited treatment, and the mineral parageneses of alkali pegmatites are not considered in detail.

In a short introduction Sørensen clarifies the complex terminology and definitions of the group and provides a brief historical review. The book is subsequently divided into six major sections concerned with petrography and petrology, regional distribution and tectonic relations, alkaline provinces, conditions of formation, petrogenesis, and economical (sic) geology. An appendix includes a useful glossary of over 400 alkaline and related rock names, and the book has been carefully indexed on the basis of rock names, subjects, geographical localities and authors.

In the first three major sections the contributions range from being largely descriptive to those with much petrogenetic content. It is difficult to do justice here to the wealth of ideas presented, but a number are of particular interest. The long duration of alkaline magmatism in certain areas is stressed by Sørensen in introducing the chapters on regional distribution. In this section, D. K. Bailey makes skilful use of African examples to examine the relationships between continental arching, rifting and magmatism, and concludes that volatile movement, with attendant heat and alkali transfer, may be important in the development of both flood and localised occurrences of alkaline rocks. The importance of structural controls over the location of magmatism in Siberia is stressed by E. L. Butakova, who also points out that in this region the development of alkaline rocks in stable areas seems to be linked with tectonic activity and calc-alkaline magmatism in adjacent fold belts. In contrast, M. Mathias does not find any obvious and simple correlation between alkaline rocks and structural features in southern Africa.

The alkaline provinces were selected to cover common rock associations, using well documented areas for which there were no readily available reviews. They are: the Kola Peninsula, South-

West Greenland, France and central Europe, the Mongol-Tuva province south-west of Lake Baikal, the Monteregian Hills in eastern Canada, Oceanic Islands and Niger-Nigeria. In several, the parental role of alkali olivine basalt or of melilite basalt is favoured, with extensive anorthosites requiring explanation in South-West Greenland and Niger. A. S. Pavlenko expresses a different viewpoint on the origins of the dominant alkali granites and miaskitic syenites of the Mongol-Tuva province. Here, the field and other evidence indicates a replacive origin for some at least of the alkaline rocks, which are seen as the climax of palingenesis of a thickened crust.

Reviewing • experimental studies, A. D. Edgar stresses the role of volatiles in alkali rock evolution (a topic also considered by L. N. Kogarko), discusses mechanisms by which thermal barriers may be crossed, and examines

# **Concepts for testing**

H. B. Barlow

Concepts and Mechanisms of Perception. By R. L. Gregory. Pp. xi+669. (Duckworth: London, September 1974.) £18.00.

This book consists of 56 articles by Richard Gregory and his collaborators. Some are only a page or two long, though the longest, and probably the most important, is a reprint of his study (with Jean Wallace) of the vision of a man who was blind from the age of a few months until he received a successful corneal graft at the age of 52. The book starts with a 30 page "Pretext" and short commentaries link and up-date each chapter. About 15 of the articles have not appeared before, but a good deal of this new material consists of descriptions of apparatus, patent specifications, or rather lightweight articles. The more substantial parts would be available to anyone with access to a good library, and it is not clear who will find it necessary or desirable to purchase this rather expensive collection.

Anyone who dips into the book will find that the articles and commentaries make light and easy reading; a delightful air of geniality pervades it. The "Pretext" especially is written with a constructive imagination that always makes it alive and interesting. But we know, since Popper and Fisher, that science advances by the brutal destruction of hypotheses, and I am not sure that the benign and gentle ideas that Gregory advances will survive for long in the vicious jungle of facts uncovered by critical psychologists.

the conditions of formation of specific minerals. Researches on homogenisation temperatures of inclusions in minerals, described by V. S. Sobolev and others, indicate temperatures in excess of 850°C during nepheline syenite crystallisation, whereas phenocrysts in effusive rocks may have commenced crystallisation at appreciably higher temperatures (>1,250°C).

Several of the contributors dealing with petrogenesis express doubts on any simple parental role of alkali olivine basalt in alkali rock genesis, although this is clearly a reasonable assumption in Oceanic Islands and in provinces such as France and central Europe, and South-West Greenland. J. L. Powell and K. Bell find that the isotopic composition of strontium may indicate derivation from continental basalt for many alkaline rocks but processes involving partial fusion of inhomogeneous source material may also be involved, as may assimilation, although not of limestone (a process also not favoured by P. J. Wyllie in a later chapter). D. K. Bailey argues strongly in favour of derivation of felsic alkaline magmas by partial melting in the deep crust. After reading the petrogenesis section one is left with the impression that relatively little is known about the nature and structure of the supposed source areas for the alkaline magmas in the upper mantle or the deep crust. It is to be hoped that this imbalance will be corrected in an extension of geophysical investigations, of the type in progress in East Africa and the Oslo Fjord area, to other alkaline provinces, and that these will be integrated with the petrological researches.

The common development of layering and other features of igneous cumulates indicate the importance of crystal fractionation in alkali rock formation, a topic given detailed consideration by R. Macdonald. The sequence of types in many alkali associations is, however, not always readily explicable in terms of crystal fractionation of a parent magma, and the suggestion by L. N. Kogarko and others that compositionally graded magma chambers may form from volatile migration along P-T gradients is welcome and deserves to be explored further.

The book contains a wide range of informative and stimulating contributions. Professor Sørensen is particularly to be congratulated on obtaining, with the help of Dr V. P. Volkov, contributions from so many Russian petrologists. The book is well produced and clearly illustrated with numerous line diagrams. It is a volume which can be thoroughly recommended to everyone interested in advanced igneous petrology.

#### APPOINTMENTS VACANT

#### DIRECTOR

Applications are invited for the position of DIREKTOR DES INSTITUTS FÜR TIERZUCHT UND TIERVERHALTEN FORSCHUNGSANSTALT FÜR LANDWIRTSCHAFT.

LANDWIRISCHAFI,

a federal research institution engaged in reproductive biology, animal behaviour and enetics. Staff of 250 including 16 scientists. Research budgeted. Facilities: 2,500 m² of laboratory space; 4 research farms (1200 ha); live stock of 1,200 cattle, 2,000 pigs, 1,000 sheep. Locations: main laboratories and 2 farms at Mariensee near Hannover; laboratory and 2 farms at Trenthorst near Lübeck.

Qualifications: Internationally established research reputation. Applicants with biochemical and physiological background should be enabled to coordinate the research programmes of the different sections.

coordinate the research programmes of the sections.
Salary: approx. 65,000 DM/annum (B 3 tenure position in government service).
To apply, send curriculum vitae, summary of research activities, list of publications and reprints before December 31, 1975 to:
Prof. Dr E. Zimmer
Präsident of Forschungsanstalt für Landwirtschaft Bundesallee 50
D 33 Braunschweig
Federal Republic of Germany
(1792)

#### THE HORMEL INSTITUTE OF THE UNIVERSITY OF MINNESOTA

UNIVERSITY OF MINNESOTA invites applications from qualified individuals for the position of EXECUTIVE DIRECTOR of The Hormel Institute which is located in Austin, Minnesota. The Executive Director is responsible for overall administration of an institute with 80-90 employees, including 20 of whom have academic rank. Candidates for this position should be recognised authorities in the lipid field, and should have at least 12 years of research experience in the field. The director is expected to maintain an active research programme.

Closing date for receipt of all materials is February 1, 1975. Send curriculum vitae, a list of publications and names of three referees to Dr J. E. Gander (Chairman, Search Committee), Department of Biochemistry, University of Minnesota, St Paul, MN 55108. (1886)

#### **BIOCHEMICAL TECHNICIAN**

Biochemical Technician required for small laboratory engaged in Metabolic Studies. Some experience with enzymes an advantage. Salary £1,800 to £2,800. Please apply with details of experience and names and addresses of two referees to: The addresses of two referees to: The Director, Alfred Chester Beatty Body Dynamics Laboratory, Brooksden, Cranbrook, Kent TN17 3DT.

(1897)

## **Senior Pharmacologist Anti-Inflammatory Research**

Applications are invited for a senior post in our Pharmacology Department in Welwyn Garden City, Hertfordshire. The department is responsible for carrying our research and screening work aimed at the development of new drugs in which the pharmacologists participate in the research programmes of interdisciplinary groups.

The senior pharmacologist we appoint will be responsible for directing the work of a team of pharmacologists engaged in anti-inflammatory research. Applicants should have a Ph.D. qualification and preferably some post-doctoral experience in anti-inflammatory research.

Our Pharmacology Department is located in new laboratories where the facilities and working conditions are excellent. Conditions of service are above average and in appropriate cases generous assistance with relocation will be available.

Roche Products Limited is part of a major international pharmaceutical firm based in Switzerland and is itself one of the leaders in the industry in the United Kingdom. If you would like to apply for this post please write for further information, and a Company booklet, to the Welwyn Personnel Manager.

Closing date for applications, December 13, 1974.

Roche Products Limited Welwyn Garden City Hertfordshire AL7 3AY

(1896)

#### INSTITUT MAX VON LAUE-PAUL LANGEVIN GRENOBLE - FRANCE

The Institut Max Von Laue-Paul Langevin operates a high flux reactor providing intense beams of neutrons for studies of condensed matter in the fields of physics, chemistry, biology and materials science. Visitors from universities and research centres in the member countries, France, Germany and the U.K., and resident scientists use the high flux beam reactor and the Institut provides scientific and technical support.

Applications are invited for the following posts at Grenoble:

#### THEORETICAL PHYSICISTS

Vacancies exist at the Institut for theoretical physicists interested in the microscopic properties of condensed matter. Successful applicants would join a theoretical physics group which complements the wide range of research studies that are conducted with neutron scattering techniques. Candidates should possess an appropriate degree and preferably have had post-doctoral experience in solid state, liquid or polymer physics.

The appointment would be for two years in the first instance with a possibility of an extension.

Salary will be according to qualifications, experience and responsibilities. Removal expenses will also be paid and assistance given in seeking accommodation.

Write for application form to: Mr D. McConville, Science Research buncil, c/o British Rail Engineering Ltd, Swindon Works, Swindon. Council, c/o British Rail Engineering Ltd, Swindon Wo Wiltshire, SN1 5BW, quoting reference and post applied for.

Completed application form should be returned by December 16, 1974. Ref: ILL/01. (1945)

#### INSTITUT MAX VON LAUE-PAUL LANGEVIN **GRENOBLE — FRANCE**

The Institut Max Von Laue—Paul Langevin operates a high flux reactor providing intense beams of neutrons for studies of condensed matter in the fields of physics, chemistry, biology and materials science. Visitors from universities and research centres in the member countries, France, Germany and the U.K., and resident scientists use the high flux beam reactor and the Institut provides scientific and technical support.

Applications are invited for the following post at Grenoble:

#### **ENGINEER-**SAMPLE ENVIRONMENT SECTION

The successful applicant will work in a team and be responsible to the Section Head for the design, acceptance tests and routine operation of special equipment (cryogenics, high pressure, high temperature) used for the control of the environment of specimens studied in the instruments of the

high flux reactor.

Applicants should possess a degree or equivalent qualification and have had some years' experience in a research laboratory. In particular they should have a good practical and theoretical knowledge of cryogenics (several years experience) and a practical knowledge of vacuum technology. A knowledge of neutron scattering physics would be an advantage. A working knowledge of French is desirable but not immediately essential as tuition will be given.

Salary will be according to qualifications, experience and responsibilities. Removal expenses will also be paid and assistance given in seeking accom-

modation.

Write for application form to: Mr D. McConville, Science Research Council, c/o British Rail Engineering Ltd, Swindon Works, Swindon, Wiltshire, SN1 5BW, quoting reference and post applied for.

Completed application form should be returned by December 16, 1974.

Ref: ILL/02 (1946)

# PLANT VIROLOGIST

£2,461 to £4,441

Applications are invited for a permanent and pensionable appointment in the Plant Pathology Division of the Department of Agriculture.

The duties involve conducting research on plant virus diseases with particular reference to diseases of grass, cereal and horticultural crops.

The successful applicant may be required to undertake teaching duties in the Department of Mycology and Plant Pathology, Faculty of Agriculture and Food Science, The Queen's University, Belfast.

The appointment may be at Senior Scientific Officer or Higher Scientific Officer level.

Senior Scientific Officer should be over 25 and under 32 years of age with a • first or second class Honours degree in a scientific or agricultural discipline pertinent to Plant Pathology and at least four years post-graduate experience in Plant Virology.

Higher Scientific Officer should be under 30 years of age with an Honours degree as above and at least two years relevant post-graduate experience.

Salary scales: Senior Scientific Officer - £3,157 to £4,441 Higher Scientific Officer - £2,461 to £3,371

Grading and starting salary will be related to qualifications and experience. A cost of living supplement is also payable.

lease write or telephone for an application form, quoting Ref. SB 308/74/N, to Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232 44300, ext. 26). Completed forms must be returned to arrive not later than December 5, 1974. (1965)

#### PENNSYLVANIA STATE UNIVERSITY

DEPARTMENT OF PHYSICS

DEPARTMENT OF PHYSICS

Assistantships are available for graduate students wishing to pursue a Ph.D. program, starting September 3, 1975. Major research areas: Solid state and surface physics, field ion microscopy, fow temperature physics, molecular spectroscopy, laser physics and nonlinear optics, vacuum and ionosphere research, acoustics, particle and Q.E.D. theory. Half-time teaching assistantships carry a stipend of \$3,852 for nine months. Quartertime summer teaching appointments and some all-year research appointments are available. Address inquiries to Prof. R. H. Good, Jr., Head, 104 Davey Laboratory, University Park, Pa., U.S.A. 16802. (1770)

#### NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of

#### TIMBER RESEARCH OFFICER

Applicants must have a degree or equivalent pro-fessional qualification in timber or structural engineering and experience in the use of timber in the mining and other industries.

The timber research officer's duties will include The timber research officer's duties will include making surveys of timber and forest products utilization by the Zambian industries including the mining industry, planning and executing applied research in the use of timber and forest products and liaising with industries on timber and forest products utilization.

Salary according to qualifications and experience on the scales:—
Senior Professional Officer

K4,680 by 240 to K5,640

Principal Professional Officer

K4,680 by 240 to K5,640
Principal Professional Officer
K5,840 by 240 to K6,800
Senior Principal Professional Officer
K7,000 by 200 to K7,600
There is a superannuation scheme for Zambians.
Non-Zambians will be paid a graduated gratuity of 20% of the total earnings in the first year. 25% in the second year and 30% in the third year of resident service. Passages will be paid for the officer, wife and minor dependent children.

while and minor dependent children.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to:—

The Secretary General,
National Council for Scientific Research,
P.O. Box CH 158,
Chelston, Lusaka,
Zambia. (1794)

#### UNIVERSITY COLLEGE LONDON DEPARTMENT OF BIOPHYSICS ELECTRON-MICROSCOPIST RESEARCH ASSISTANT

required to work with Professor R. Miledi on problems in Neurobiology, which forms part of a long-term Project supported by the M.R.C.

Preference given to applicants with experience of freeze-etching or analytical electron-microscopy. Salary within Lecturer scale plus London Allow-

Applications with curriculum vitae and names and addresses of two referees to Mrs K. Garnons-Williams, Biophysics Dept (N), University College London, Gower Street, London WC1E 6BT. (1883)

#### CLINICAL MICROBIOLOGIST (Ph.D.) CANADA

The Hamilton District Programme in Laboratory Medicine requires a Clinical Microbiologist to be located at the Hamilton General Hospital. The appointee should possess a Ph.D. in clinical microbiology. Training and experience in Mycology would be an advantage. The appointment entails responsibilities in the supervision of the clinical laboratory and teaching in the Microbiology/Infectious Disease Educational Programmes of the Faculty of Health Sciences, McMaster University and the District Programme in Laboratory Medicine. Facilities for research are available. The position carries an appointment in the Department of Pathology, McMaster University, appropriate to qualifications and experience.

Applications and experience.

Applications, enclosing curriculum vitae, transcript, and the names of three referees, to:—
Dr. I. O. Stewart,
Head of Microbiology, and District
Co-ordinator for Microbiology/Infectious Disease,
Hamilton General Hospital,
Hamilton, L8L 2X2,
Ontario, Canada Hamilton, L8L 2 Ontario, Canada.

(1954)

#### ASSISTANT PROFESSORS (Biological Sciences)

(Biological Sciences)

Several positions are open for biologists with promise of creative and dynamic research programs in plant tissue culture, immunobiology, developmental biology, biochemical taxonomy, neurobiology, behavioral or human genetics. Share in teaching large elementary course, or pre-professional courses (embryology, animal physiology), and develop advanced courses in areas of speciality. Send resume and references to: A. Eisenstark, Director, Division of Biological Sciences, University of Missouri, Columbia, Missouri 65201 U.S.A. University of Missouri of Missouri is an affirmative action, equal opportunity employer. (1953)

#### TERRESTRIAL PLANT ECOLOGIST/SOCIOLOGIST

Dalhousie University has a vacancy from July 1, 1975 for a plant ecologist/sociologist. Qualifications: Ph.D. and proven ability in teaching and research. Duties include teaching at the undergraduate and graduate levels, and developing a vigorous research program in terrestrial plant ecology. There is a possibility for major research support in interdisciplinary forest studies. Salary and rank negotiable; a senior appointment is possible. Curriculum vitae and names of three referees to be sent to: Chairman, Department of Biology, Dalhousie University, Halfax, N.S. Canada B3H 4J1. Closing date: when position filled. (1955)

#### YORK UNIVERSITY DEPARTMENT OF CHEMISTRY

DEPARTMENT OF CHEMISTRY

Applications are invited for a senior position available July 1, 1975, in the field of chemical physics with experience in laser photochemistry. The successful candidate will play a leading role in establishing a major research centre in this field. The appointment will be made at the rank of Full or Associate Professor. Salary negotiable and commensurate with rank. Send curriculum vitae, reprints and names of three referees to Professor G. O. Aspinall, Department of Chemistry, York University, Downsview, Toronto, Ontario M3J 1P3, Canada. (1957)

#### UNIVERSITY OF BERNE DEPARTMENT OF PAEDIATRICS

Position vacant for RESEARCH BIOCHEMIST in Switzerland. Required: Experience in modern separation techniques for proteins and glycopro-

teins.

Salary according to experience. Team-work in a Medical Research Unit.

Applications should be sent to: Professor B. Hadorn
Gastrointestinal Unit

University Children's Hospital Freiburgstrasse 23

3010 BERNE (Switzerland).

(1958)

#### UNIVERSITY OF ILLINOIS AT **URBANA-CHAMPAIGN** PLANT BIOPHYSICIST. ASSISTANT PROFESSOR

for Fall 1975. Joint appointment in Departments of Physiology & Biophysics (Biophysics Division) and Botany. Postdoctoral research experience, publications essential. Teaching includes developing a plant biophysics course. Apply to: Dr. Thomas G. Ebrey, 524 Burrill Hall, University of Illinois, Urbana, Illinois 61801. The University of Illinois at Urbana-Champaign is an Affirmative Action/Equal Opportunity Employer and encourages applications from members of minority groups and women. (1959)

#### WITHINGTON HOSPITAL

#### MANCHESTER M20 8LR

The National Reference Laboratory for Anticoagulant Control Reagents requires a MEDICAL LABORATORY TECHNICIAN. A.I.M.L.T. qualification or good honours degree in applied science necessary. Appointee will be trained in basic routine blood coagulation procedure and will participate in routine work, research and development. Good career prospects.

Applications in writing naming two referees to the Hospital Secretary, quoting reference B46. (1978)

#### INSTITUT MAX VON LAUE-PAUL LANGEVIN GRENOBLE - FRANCE

The Institut Max Von Laue-Paul Langevin operates a high flux reactor providing intense beams of neutrons for studies of condensed matter in the fields of physics, chemistry, biology and materials science. Visitors from universities and research centres in the member countries. France, Germany and the U.K., and resident scientists use the high flux beam reactor and the Institut provides scientific and technical support.

Applications are invited for the following post at Grenoble:

#### TECHNICIANS FOR THE NEUTRON BEAM EXPERIMENTS

The Institut is currently forming a small technical group within the general service section with a view to ensuring the maximum exploitation of instruments. The group is expected to collaborate with engineers on the design of new neutron beam experimental equipment, assist with its installation and testing and collaborate with the physicists and technicians on the established instruments when required.

Applicants should possess O.N.C. or equivalent qualifications and have had research laboratory experience in some of the following areas: high vacuum, high temperatures, high pressures, cryogenics, mechanical and electrical engineering. A knowledge of French is desirable but not essential.

Salary will be according to qualifications, experience and responsibilities. Removal expenses will also be paid and assistance given in seeking accommodation.

Write for application form to: Mr D. McConville, Science Research Council, c/o British Rail Engineering Ltd, Swindon Works, Swindon, Wiltshire, SN1 5BW, quoting reference and post applied for.

Completed application form should be returned by December 16, 1974. Ref: ILL/03

# Neuropharmacologist

We would like to appoint a Pharmacologist with post doctoral research experience to a position in our CNS unit. The successful candidate will have a thorough knowledge of laboratory methods for the detection and evaluation of compounds which interact with the central nervous system and will be keen to generate and test new ideas in collaboration with chemists, biochemists and clinicians.

This appointment could be attractive to a scientist who has held a post in a university or in industry.

Conditions of service, prospects and assistance given in moving home, are designed to attract and retain staff of this high calibre and would be discussed in detail at interview.

Applications in writing, giving brief details of age, experience and qualifications, should be sent to:

M. F. Losse, Personnel Officer Imperial Chemical Industries Limited Pharmaceuticals Division Mereside, Alderley Park Nr. Macclesfield, Cheshire.

(1977)

# SCOTTISH SOCIETY FOR RESEARCH IN PLANT BREEDING CYTOLOGIST

Applications are invited for the post of Scientific Officer/Higher Scientific Officer in the Cytology Laboratory of the Scottish Plant Breeding Station. The person appointed will be required to take charge of the Laboratory, which provides a cytology service to breeders working on cereals, forage grasses and potatoes.

The Scottish Plant Breeding Station is financed by the Department of Agriculture and Fisheries for Scotland under scientific advice from the Agricultural Research Council and is a component of the Agricultural Research Service within which common conditions of service apply. It is located about 1½ miles south of Edinburgh City boundary, and comprises modern laboratories, glasshouses, land and other facilities.

Qualifications: Minimum, H.N.C. pass degree or equivalent in Botany, agricultural Botany, Plant Science or Biology and preferably with training or experience in general microscopy and chromosome studies. At least five years' appropriate scientific experience are required for appointment to Higher Scientific Officer.

Salary: depending on qualifications and experience. Scientific Officer—£1,592 to £2,675 Higher Scientific Officer—£2,461 to £3,371. The post is superannuable.

Application forms from the Secretary, Scottish Plant Breeding Station, Pentlandfield, Roslin, Midlothian, EH25 9RF to be returned not later than December 6, 1974.

Applicants from the Agricultural Research Service should submit their application through their present Director if they wish to be considered for the award of "public interest" transfer terms. (1962)

# MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH DIVISION OF CYTOPATHOLOGY CELL BIOLOGIST OR ELECTRON MICROSCOPIST

ELECTRON MICROSCOPIST

Applications are invited from young postdoctoral scientists (up to the age of 27 years) for
a position with a group investigating the fine
structure and properties of cellular membranes,
particularly in relation to virus infections. The
successful applicant will be involved in biological
preparative methods; experience in immunolabelling, auto-radiography, thin-sectioning, or
cryo-techniques for electron microscopy would
therefore be an advantage. The appointment
will be for up to three years and will be in the
salary range £2,412 to £3,636 p.a. according to
age and qualifications (plus London and threshold
allowances). Superannuation provision is under
F.S.S.U.

Applications giving details of qualifications. ex-

F.S.S.U.

Applications giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before December 14, 1974. (1960)

# PHYSICAL CHEMIST

#### (M.Sc. or Ph.D.)

We have a vacancy in our new Research and Development Centre at Paisley for a young physical chemist, preferably with some experience of colloid chemistry.

The successful candidate will join a small research team actively engaged in studies of the physico-chemical properties of organic pigments. He will be concerned primarily with the properties of dispersions in liquid media. There is great scope for original thought and enthusiasm in this vital position. It is essential that we continue to improve our knowledge of the underlying mechanisms which control this young and growing technology.

Our laboratories are well equipped to make appropriate physicochemical and rheological measurements and excellent back-up analytical facilities are available, including electron microscopy and X-ray diffraction. Complementary surface chemical studies are in progress using gas/ vapour adsorption and calorimetric techniques.

We anticipate that suitable applicants will possess at least an M.Sc. degree, but preferably a Ph.D., and will be aged around 25/30 years.

An attractive starting salary will reflect the importance of this position, and there is a substantial range of fringe benefits. Generous assistance will be given with removal and relocation expenses where applicable.

CIBA-GEIGY (UK) Limited is a major subsidiary of CIBA-GEIGY Limited, the Swiss based international enterprise which has its headquarters in Basle. CIBA-GEIGY has a reputation for high quality products in the areas of agrochemicals, dyestuffs, plastics, pigments and industrial chemicals, pharmaceuticals, photographic materials and garden, household and beauty care products.

Please write with brief details of qualifications, research experience and present position to:—

Mr. D. Glenn,
Senior Personnel Officer,
CIBA-GEIGY (UK) Limited,
Pigments Division,
Hawkhead Road,
Paisley PA2 7BG.

# CIBA-GEIGY

(1948)

#### UNIVERSITY OF NATAL DEPARTMENT OF GEOLOGY PIETERMARITZBURG

Applications are invited from suitably qualified persons for appointment to the post of

#### LECTURER IN STRUCTURAL GEOLOGY, MINERALOGY AND CRYSTALLOGRAPHY

The salary scales attached to the post are: R4,800 by 300 to R6,900 plus 15% pensionable allowance. A general upward revision of salary scales is expected immediately.

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Treasury regulations,

Application forms, further particulars of the post and information on pension, medical aid, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, South Africa, with whom applications, on the prescribed form, must be lodged not later than January 17, 1975, quoting reference Adv. 139/74. (1969)

#### ROYAL HOLLOWAY COLLEGE (UNIVERSITY OF LONDON) Egham Hill, Egham, Surrey.

#### EXPERIENCED ELECTRONICS TECHNICIAN (GRADE 4)

Required in the Physics Department for 1 year only. Salary in the scale £1,848 to £2,163. Applications together with the names and addresses of two referees should be sent to the Personnel Officer (N) as soon as possible. (1970)

#### UNIVERSITY OF READING DEPARTMENT OF PHYSIOLOGY & BIOCHEMISTRY

#### RESEARCH DEMONSTRATOR

RESEARCH DEMONSTRATOR
required immediately to carry out research for a higher degree in any one of the following subjects: steroid biochemistry of the mature and immature mammalian testis and epididymis; glutamate and glutamine metabolism in the foetal and neonatal sheep; fatty acid synthesis in the rabbit mammary gland; organic constituents of egg shells; protein and amino acid metabolism in the growing rabbit; determination of the primary lesion of heat damage in the testis; physiological studies of the avian oviduct; study of the nitrogen metabolism in the coprophagous mammal. Salary £1,122 by 54 to £1,230 p.a. plus threshold supplement. Candidates should have a good second class Honours degree in a relevant subject. The post will be for three years with the possibility of extension; about 12 hours demonstrating per week during term time. Enquiries and/or applications, with the names of 2 academic referees, should be addressed to Professor G. M. H. Waites, Department of Physiology and Biochemistry, The University, Whiteknights, Reading RG6 2AJ. Telephone Reading 85123 ext. 7675. (Ref. TN 95). Closing date: December 16, 1974. (1971)

#### DANISH SPACE RESEARCH INSTITUTE **COPENHAGEN**

invites applications for a research position in the cosmic ray group. Ph.D. degree is required.

The main interests of the group lie in the study of the isotopic composition of galactic cosmic radiation.

Applicants should have a proved competence and a strong interest in the development of new experimental techniques. Some experience in initiating and directing research programmes would be useful.

Salaries for research workers in Denmark are approximately equivalent to those prevailing in the U.K. They follow rules set by government and depend on qualifications.

Appointment will be for one year with possibility of renewal.

possibility of renewal.

Interested persons are asked to send a resume of their experience and references to:

B. Peters, Director

Danish Space Research Institute

Lundtoftevej 7

2800 Lyngby, Denmark (1975)

#### NOTTINGHAM AREA GENETIC SERVICE Maternity Unit and City Hospital

# **BASIC GRADE** SCIENTIFIC OFFICER

Applicants should possess a degree in Biology and preferably have a background of genetics. The post will involve diagnostic analysis of human chromosomes from long and short-term tissue cultures.

Salary scale: £2,046 to £2,562 for 1st and 2nd class Honours degrees; £1,689 to £2,562 for ordinary degrees.

Further information can be obtained from Dr Cooke, Tel: 68111 Ext. 2785.

Application forms from the Personnel Department, Sherwood Hospital, Hucknall Road, Nottingham. Tel: 600459 any time.

(1961)

#### Applications are invited from graduates in chemistry for

#### FREE-LANCE EDITORIAL WORK

on manuscripts and proofs, Essential requirements are English as mother-tongue, an appreciation of good English style, and a meticulous eye for detail. Applications, in writing, with details of experience and qualifications (including specialist field of study) should be addressed to Miss T. Sijpesteyn, Elsevier Scientific Publishing Company, P.O. Box 330, Amsterdam, The Netherlands.

#### ROYAL HOSPITAL FOR SICK CHILDREN EDINBURGH

#### CYTOGENETICIST

There is a vacancy for a graduate within the cytogenetic unit of this hospital. The unit provides a diagnostic cytogenetic service for a number of hospitals and is responsible for the amniotic fluid cell culture for the Lothians area.

Experience in cytogenetics, and preferably tissue culture, is essential. Opportunities for a higher degree may be available.

Salary within the range of £1,497 to £2,694 depending on qualifications and experience.

Applications stating experience and the names and addresses of two referees to the Sector Administrator, Royal Hospital for Sick Children, 1 Rillbank Terrace, Edinburgh EH9 1LN.

# ■ Lothian Health Board

#### SCOTTISH SOCIETY FOR RESEARCH IN PLANT BREEDING

#### POTATO BREEDER/NEMATOLOGIST

Applications are invited for the post of Scientific Officer/Higher Scientific Officer in the Potato Department of the Scottish Plant Breeding Station to work on (a) breeding projects for the transfer of genetic resistance to potato cyst eelworm to cultivated potatoes and (b) studies of resistance, pathogenicity and host-parasite relations.

The Scottish Plant Breeding Station is financed by the Department of Agriculture and Fisheries for Scotland ander scientific advice from the Agricultural Research Council and is a component of the Agricultural Research Service within which common conditions of service apply. It is situated about 1‡ miles south of Edinburgh City boundary, and comprises modern laboratories, glassshouses, land and other facilities.

Qualifications: 1st or Upper 2nd class honours degree in Plant Science, Zoology, Biology or Genetics. At least two years' postgraduate research, preferably in genetics or nematology, are required for appointment to a Higher Scientific Officer.

Salary: depending on qualifications and experience. Scientific Officer—£1,592 to £2,675 Higher Scientific Officer—£2,461 to £3,371. The post is superannuable.

Application forms from the Secretary, Scottish Plant Breeding Station, Pentlandfield, Roslin, Midlothian, EH25 9RF to be returned not later than December 6, 1974.

Applicants from the Agricultural Research Service should submit their application through their present Director if they wish to be considered for the award of "public interest" transfer terms. (1963)

# HIGHER SCIENTIFIC OFFICER £2,461 to £3,371

Applications are invited for the post of Higher Scientific Officer in the Field Botany Research Division of the Department of Agriculture.

The duties will include responsibility for seed certification and seed testing.

Applicants must be under 30 years of age on December 31, 1974 and have a degree in Agriculture or an appropriate Agricultural Science; or an H.N.D. in Agriculture; or an equivalent qualification acceptable to the Civil Service Commissioners. Some knowledge and experience of seed technology is essential.

Starting salary will be related to qualifications and experience. A cost of living supplement is also payable. There are prospects of promotion to Senior Scientific Officer (£3,157 to £4,441).

Please write or telephone for an application form, quoting Ref. SB 309/74/N, to Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232 44300, ext. 26). Completed forms must be returned to arrive not later than December 5, 1974. (1967)

#### ROYAL VICTORIA HOSPITAL DEPARTMENT OF MICROBIOLOGY PRINCIPAL SCIENTIFIC OFFICER

Applications are invited from those holding a degree in a biological science. The person required must be widely experienced in Microbiology including automation and microbiological assay techniques and be able to evaluate new methods, including quality control in relation to diagnostic bacteriology and secology.

bacteriology and serology.

A candidate with less experience may be given an interim appointment as a Senior Scientific Officer.

#### SALARY SCALE: £4,482 to £5,796 per annum.

Application forms may be obtained from the District Personnel Department, Eastern Health and Social Serwices Board, North and West Belfast District, Royal Victoria Hospital, Grosvenor Road, Belfast BT12 6BA, to be returned by Friday, December 13, 1974. (2003)

#### HISTOLOGY TECHNICIAN

required for Pharmacological and Toxicological Laboratory. Experience in the preparation and processing of animal tissues essential. Good working conditions, Pension and Assurance Scheme. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (1996)

# UNIVERSITY OF READING WOLFSON RESEARCH PROJECTS

Applications are invited for research officers—salaries in the range £2,000 to £4,000 per annum—for two projects supported for a four year period by grants from the Wolfson Foundation for the development of U.K. resources, viz:—(i) Oilseed utilisation—edible oil and protein; (ii) leaf protein for human use. Candidates should have degrees in a suitable subject, such as chemistry, biochemistry, or chemical engineering, research experience and preferably some industrial experience. There are vacancies also for graduate or non-graduate research assistants.

Applicants should send a detailed statement

Applicants should send a detailed statement of career together with a short covering letter and the names of two referees to Professor R. Aylward, Department of Food Science, University of Reading, London Road, Reading RGI 5AQ. (Ref: MN 55). (1972)

#### UNIVERSITY OF KENT AT CANTERBURY RESEARCH ASSISTANT IN BIOCHEMISTRY

Applications are invited for the post of Research Assistant in Biochemistry to work on aspects of the control of amino-acid and carbohydrate metabolism by hormones and other effectors in in vitro systems under the supervision of Dr C. I. Pogson. Applicants should have a degree in Biochemistry or a related subject.

chemistry or a related subject.

The appointment, which is supported by the Medical Research Council, will be for two years on the scale £1,317 to £1,782 (Eligible for threshold payments). Application forms and particulars may be obtained from the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH. Please quote ref. A74/74. Closing date for applications December 6, 1974. (1979)

### THE HANNAH RESEARCH INSTITUTE

#### HIGHER SCIENTIFIC OFFICER

required to assist with work on the metabolism of polyunsaturated fatty acids by ruminant animals. Candidates should have a degree or H.N.C. in Chemistry or Biochemistry with at least 5 years' appropriate post qualifying experience.

Starting salary in the range £2,461 to £3,371 plus Threshold Agreement according to qualifications and experience. The post is pensionable.

Applications giving age, curriculum vitae and the names of three referees should be forwarded to The Secretary, The Hannah Research Institute, AYR KA6 5HL by December 10, 1974. (1980)

# UNIVERSITY OF LEICESTER DEPARTMENT OF GENETICS (Head of Department: Professor R. H. Pritchard)

Applications are invited for a post of

#### LECTURER

The person appointed will participate in the teaching of genetics to both medical students and those studying for the B.Sc. in Biological Sciences. Candidates must have a broad knowledge of genetics and preference will be given to those who combine this with postdoctoral experience in some aspect of nucleic acid technology.

Initial salary according to qualifications and experience within the range £2,118 to £4,896 a year plus threshold payments, at present £167.04, plus Superannuation. Further particulars from the Registrar, to whom applications should be sent quoting reference NLG by January 5, 1975.

(1986)

#### ST THOMAS'S HOSPITAL MEDICAL SCHOOL (University of London)

#### London SE1 7EH RESEARCH ASSISTANT

required for three year Virology/Immunology project. Suitable for PhD candidate.

Written applications to Dr J. E. Banatvala from whom further particulars may be obtained.

#### THE UNIVERSITY OF **MANCHESTER**

KEEPER OF ZOOLOGY

Applications invited for the above post in the MANCHESTER MUSEUM. Duties to commence on October 1, 1975. Candidates should be graduates in Zoology and should have experience in curating zoological collections, the most important of which in the department belong to mollusca and birds. The Diploma of the Museums Association would be an advantage. Salary range £2,580 to £4,896 p.a. F.S.S.U. Further particulars and application forms (returnable by January 1, 1975) from the Registrar, The University, Manchester, M13 9PL. Quote ref: 239/74/N. (1987)

#### UNIVERSITY OF CAMBRIDGE DEPARTMENT OF APPLIED BIOLOGY

#### FIELD STATION SUPERINTENDENT

Vacancy exists for an Assistant Technical Officer to be superintendent of the Department's Applied Biology Field Station. Candidates should have had experience of experimental field station and glasshouse operations and preferably possess an appropriate qualification. Tenure three years first instance; extendable. Pensionable salary in scale £1,941 to £3,108 (7 increments). Starting point determined by age, qualifications and experience. Superannuation with F.S.S.U. Assistance with removal expenses. Further details from and applications in writing giving full particulars of qualifications and experience and names and addresses of not more than three referees to the Secretary, Faculty Board of Biology 'A', Department of Applied Biology, Downing Street, Cambridge, CB2 3DX, not later than December 20, 1974. (1991)

#### THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CHILD HEALTH RESEARCH ASSISTANT

Applications are invited for the above post from science graduates. Work in the Department includes clinical and animal studies on development in the infant of renal and respiratory control and the study of the effect of anti-tumour agents on growth. Salary range £1,905 to £2,247. Further particulars from: The Registrar and Secretary, The University, Sheffield \$10 2TN, to whom applications should be sent by December 6, 1974. Quote Ref. 151/G. (1992)

#### PUBLIC HEALTH LABORATORY SERVICE

#### BACTERIAL METABOLISM RESEARCH LABORATORY

Applications are invited from biochemists/
chemists with a Ph.D. and an interest in
bacteriology for work on the identification of
minor faecal bile acids as part of a study of the
role of bacteria in the causation of intestinal cancer. The laboratory is located at Colindale and is
well equipped. The appointment is for a limited
period. N.H.S. salary scales and terms and conditions of service. Applications to: Professor R. E. O.
Williams, Public Health Laboratory Service Board,
Lower Entrance, Colindale Hospital, Colindale
Avenue, London NW9 5FO. Lower Entrance, Colindale Avenue, London NW9 5EQ. Hospital, Colindale (1994)

#### THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London) DEPARTMENT OF IMMUNOLOGY

Applications are invited for a postdoctoral research assistant to work on the immune response of mice to parasites. Salary up to £2,580 per annum plus London allowance and superannuation under F.S.S.U.

Applications including curriculum vitae and the names and addresses of two referees should be submitted to Professor I. M. Roitt, Department of Immunology, Arthur Stanley House, 40-50 Totenham Street, London WIP 9PG by December 15, 1074 (1995)

# SCIENTIFIC OFFICERS (Biometrics)

£1,592 to £2,675

Applications are invited for a permanent and pensionable post in the Biometrics Division of the Department of Agriculture, Newforge Lane, Relfast

Applicants must be under 27 years of age on December 31, 1974 and have (1) a Degree, H.N.C. or equivalent qualification in Computing, Mathematics or Statistics; or (2) Stage I (formerly Part II) of the Examination leading to membership of the Institute of Statisticians.

The Biometrics Division supplies a consultant service to research workers of the Department on the statistical aspects of design and analysis of experiments and surveys. The post will be concerned with (a) the supervision of Assistant Scientific Officers who process research data collected by officers of the Department and post-graduate research students at the Agricultural and Food Science Centre, Newforge Lane, Belfast; and (b) the application of existing computer packages, the development of new computer programs and in the methodology of the direct capture of data for analytical procedures.

Starting salary will be related to qualifications and experience. A cost of living supplement is also payable.

There are prospects of promotion to Higher Scientific Officer (£2,461 to £3,371), Senior Scientific Officer (£3,157 to £4,441) and Principal Scientific Officer (£4,227 to £5,550).

Please write or telephone for an application form, quoting Ref. SB 314/74/N to Civil Service Commisssion, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms should be returned to arrive not later than December 5, 1974.

DEPARTMENT OF NUCLEAR MEDICINE

# PHYSICIST (Basic Grade)

required for Department engaged in a wide range of tests involving use of radioactive substances. The successful applicant will be initially concerned with commissioning a shadow-shield whole body counter, in collaboration with other physics staff, and carrying out measurements on patients.

Whitley Council conditions of service apply. Salary scale £1,689 to 22,562 p.a. plus London Weighting at £126 p.a. and current Threshold payments. Point of entry on scale will be determined by qualifications and experience.

Applications to Mr C. J. Hill, Personnel Department, Fulham Palace Road, Hammersmith, London, W6 8RF. Tel: 748 2050 ext. 2992. Please quote ref. 021. Forms should be returned by Décember 2, 1974.

#### MEDICAL RESEARCH COUNCIL CLINICAL AND POPULATION CYTOGENETICS UNIT SCIENTIST

A vacancy exists in the Experimental Studies Section of the above Unit for a research scientist, who will be principally concerned with the genetics/cytogenetics of human/murine hybrid cells, with emphasis on the mapping of human genes by somatic cell

The minimum qualification is an honours degree 2(1) in a biological science, although preference will be given to applicants with a Ph.D. or equivalent postgraduate experience. Previous experience of mammalian cell culture would be an advantage, but is not essential. Salary, dependent upon age, qualifications and experience will be on a scale £2,019 to £3,636 or £4,896 with F.S.S.U. benefits.

Applications in writing by December 16, 1974, giving full personal particulars and names of two referees, to the Administrative Officer, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 (2XU.

The Australian Government Department of Minerals and Energy invites applications for the position of

# Director Bureau of Mineral Resources Geology and Geophysics

#### The Organisation

The Bureau, which forms part of the Department of Minerals and Energy, is the Australian Government's national earth sciences organisation. It carries out geological, geophysical and mineral resources surveys over most of Australia, its continental margin and its territories; undertakes experimental studies and research in geology and geophysics; and makes basic investigations of the earth's magnetic and gravitational fields, and in seismology and volcanology.

The Bureau currently has a staff of about 600, including 280 professional staff, mainly geologists and geophysicists. Headquarters are in Canberra, with appropriate research and laboratory facilities, and observatories and field stations are maintained in Darwin, Melbourne, Perth, Port Moresby and Antarctica. This year's budget is \$A4,500,000.

#### Duties

To direct the activities of the Bureau of Mineral Resources, which are to carry out geological, geophysical and geochemical surveys and research, and publish the results, to obtain basic information on and review the geology of Australia and its mineral resources.

#### Qualifications

Wide experience in carrying out and directing investigations in the earth sciences and in mineral resources. Administrative ability of a high order.

Appropriate academic qualifications.

Salary \$21,417 (Australian) (at present exchange rate £1 = \$A1.79 approx.)

#### Location Canberra.

Conditions of Service include Four weeks annual leave plus bonus, liberal sick leave, three months furlough after ten years service, removal expenses to Canberra.

#### Appointment

Permanent appointment to the Australian Public Service is available to British subjects eligible for permanent residence in Australia who will contribute to a comprehensive superannuation scheme after appointment.

Temporary engagements for fixed periods may be considered.

Enquiries, or applications giving full details of qualifications and experience and names of referees, should be forwarded to: The Secretary, Department of Minerals and Energy, P.O. Box 5, CANBERRA A.C.T. 2600 Australia. Closing date 13th December 1974.

#### **PHARMACOLOGIST**

experienced, with veterinary or medical qualifications preferred, required for pharmacological research and toxicological studies of compounds of potential therapeutic importance. Excellent opportunities advancement in modern, well-equipped laboratory, also vacancies for New Graduates as trainees. Pension and Assurance Scheme. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB.

(1997)

#### UNIVERSITY OF NAIROBI-KENYA

UNIVERSITY OF NAIROBI—KENYA

Applications are invited for posts of (a) 2
SENIOR LECTURERS and (b) 3 LECTURERS
IN DEPARTMENT OF PHARMACY. Applicants
for (a) should have a degree in Pharmacy and a
higher degree in either Pharmacology and Toxicology or in Pharmacy. Preference will be given
to those with previous teaching at university
level and who have much research experience in
their fields. Applicants for (b) should have a
degree in Pharmacy and a postgraduate degree in
any of the following:—Pharmacy and Toxicology;
Pharmacognosy; Pharmaceutics; Pharmaceutical
Chemistry; Pharmacy. Pharmacists who are interested in these jobs will be considered for
Assistant Lectureship. Appointees will be expected
to teach both undergraduates and postgraduates
and carry out research in their fields. Salary
scales: Senior Lecturer K£2,256 to K£3,036 p.a.
Lecturer K£1,260 to K£2,580 p.a. Assistant
Lecturer K£1,260 to K£1,440 p.a. (K£1=£1.19
sterling). The British Government may supplement
salaries of Senior Lecturers and Lecturers in range
£900 to £1,752 p.a. (sterling) for married appoint
ees of £204 to £948 p.a. (sterling) for single
appointees (normally free of all tax) and provide
children's education allowances and holiday visit
passages. This supplementation is unlikely to be
applied to appointments at Assistant Lecturer
level. F.S.S.U. Family passages; various allowances. Detailed applications (2 copies) including
a curriculum vitae and naming 3 referees, should
be sent by airmail, not later than December 23,
1974 to Registrar, University of Nairobi, P.O. Box
30197, Nairobi, Kenya. Applicants resident in
U.K. should also send 1 copy to Inter-University
Council, 90/91 Tottenham Court Road, London
WIP ODT. Further particulars may be obtained
from either address. (1999)

#### UNIVERSITY OF PAPUA **NEW GUINEA**

NEW GUINEA

Applications are invited for LECTURESHIP IN PHYSICAL GEOGRAPHY to teach courses at the introductory and advanced levels. Preference will be given to candidates with interests in Geomorphology, Climatology or applied aspects of the subject. The ability to help in courses in geographical techniques and some experience in aerial photograph interpretation, are desirable. Ample field opportunities exist, and the Department has its own 4-wheel drive vehicle, boat and the normal complement of equipment. Salary scale: (including overseas allowances) A\$9,174 to A\$11,862 p.a. plus A\$360 p.a. dependants allowance (£1 sterling=A\$1.78). Conditions include provision of housing, study leave, annual leave fares, F.S.S.U. Applications (2 copies) should include particulars of age, nationality, marital status, academic record, qualifications and experience, names and addresses of three referees, a recent small photograph and an indication of estimated starting date. Further details and conditions of appointment are available from K. R. Long, Secretary, P.O. Box 4820, University, Papua, New Guinea. Closing date December 20, 1974. (1998)

#### UNIVERSITY OF DURHAM DEPARTMENT OF MATHEMATICS

Applications are invited for the post of POST-DOCTORAL SENIOR RESEARCH ASSISTANT to work on numerical methods for solving a class of integrodifferential equations arising in atomic scattering theory. The post is tenable for two years from April 1, 1975, Applicants should have suitable research experience in numerical analysis.

Starting salary £2,055 plus threshold payments and F.S.S.U. benefits.

Applications (3 copies) naming three referees, should be sent by December 12, 1974 to the Registrar and Secretary. Science Laboratories, South Road, Durham, DHI 3LE, from whom further particulars may be obtained. (2004)

#### CHAIR OF ANATOMY

#### UNIVERSITY OF NORTH CAROLINA

Applications and nominations are invited for the position of Professor and Head of the Department of Anatomy in the School of Medicine. Candidates must have a generally recognised record of important scientific contributions and a continuing commitment to vigorous investigative activity. It is expected that a candidate will have a broad background in anatomy and cell biology. The department has responsibility for teaching of gross and microscopic anatomy, neurobiology, reproductive biology and embryology in the Schools of Medicine and Dentistry and to Allied Health Disciplines. The successful candidate therefore must be seriously interested in medical and paramedical education and be prepared to assume active leadership in developing and implementing innovative and effective teaching programs for these areas and for graduate students.

Interested persons may obtain further informa-

these areas and for graduate students.

Interested persons may obtain further information or submit letters of application or nominations accompanied by a detailed curriculum vitae to CHAIRMAN, ANATOMY SEARCH COMMITTEE, DEAN'S OFFICE, UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE, CHAPEL HILL, NORTH CAROLINA 27514. An equal opportunity, affirmative action employer. (2006)

The BOTSWANA AGRICULTURAL COLLEGE, situated 7 miles from Gaborone, invites applications for a

#### SENIOR INSTRUCTOR

to head the Crops Section and manage both the theoretical and practical teaching of crop husbandry, horticulture and veld management as part of the 2-year Agriculture Certificate Course which approximates to the U.K. National Certificate in Agriculture.

Candidates should have a Diploma in Agriculture or allied subject. If possible they should have teaching experience and have had relevant experience in a developing country.

The post is tenable for 2-3 years commencing as soon as possible.

Salary in range £2,350 to £4,502 p.a. inclusive of a normal tax-free supplement paid by the British Government to citizens of, and permanently resident in, the U.K.

Benefits include a 25% terminal gratuity on the basic salary; free passage; education allowances; holiday visit passages; subsidised accommodation; generous leave and in certain circumstances, an appointment grant and interest free car loan.

Apply for further details to the Appointments Officer, T.E.T.O.C., (The Council for Technical Education and Training for Overseas Countries), 35/37 Grosvenor Gardens, London, SWIW 0BS.

(2005)

# THE POLYTECHNIC OF CENTRAL LONDON

SCHOOL OF ENGINEERING AND SCIENCE

#### RESEARCH ASSISTANT

£1,544 to £1,654 plus Threshold Agreement

for the Physics Unit. The successful candidate will investigate the solubility of deuterium in vanadium using ultra-high vacuum techniques and use X-Ray crystallographic methods to determine the strain produced in the metal lattice by the dissolved deuterium. He/she will be expected to register for the degree of Ph.D. Applications are invited from honour graduates.

Details and application form from The Establishment Officer, PCL, 309 Regent Street, London W1R 8AL. Tel: 01-580 2020 Ext. 212. (2017)

# Opportunity Overseas

# Sierra Leone

### **Production Manager (Forestry)**

At the Forest Industries Corporation, to carry out stock surveys of exploitable timber trees; plan and execute log extraction programmes; organise conversion and seasoning in the sawmill and where necessary assist in marketing timber produce; organise the operation of the furniture factory and provide advice and guidance to a counterpart.

Applicants should have experience in the prescribed duties of the post with some experience of furniture manufacture or similar type of wood processing. Appointment three years. Salary of not less than £6,000 p.a. plus a variable tax-free allowance in scale £1,005 to £2,500 p.a.

Other benefits include paid leave, free family passages, children's education allowances and free accommodation and medical attention. Applicants should normally be citizens of and permanently resident in the United Kingdom.

For full details and an application form please apply giving age and brief details of qualifications and experience to:-

# Find your place in British Gas

# SCIENTIST/ENGINEER

The Physics Division at London Research Station has a vacancy for a Scientist/Engineer to work on the measurement and prediction of thermodynamic properties of natural gas mixtures. These measurements are necessary for the efficient design and operation of systems for the liquefaction, storage, transmission and distribution of natural gas at high temperatures.

Candidates should have a good honours degree in Science or Engineering; starting salary will be according to qualifications and experience, but will be at a point on scales which rise to £4,197, plus threshold supplement.

For further details and an application form, write to the Research Secretary, British Gas, London Research Station, Michael Road, Fulham, London SW6 2AD, quoting 4010/15/NA.

(2024)

**BRITISH GAS** 

#### ROYAL ASTRONOMICAL SOCIETY LEVERHULME VISITING FELLOWSHIPS IN ASTRONOMY 1975–1976

The Council of the Royal Astronomical Society is prepared to receive applications for Leverhulme Visiting Fellowships in the academic year 1975-76 (or the calendar year 1976). These awards are open to scholars from the Commonwealth and foreign countries, with a preference for the latter and for those who have not previously had the opportunity of an extended stay in the U.K., who wish to undertake a year's study in any branch of astronomy at a university or another approved institution in the United Kinedom.

Not more than two such Fellowships will be available. The stipend attaching to an award will be in the range £2,600 to £3,000. A contribution towards the cost of the successful applicant's travelling expenses will be made.

Application forms, which must be completed and returned by January 31, 1975, may be obtained from: The General Secretary, Royal Astronomical Society, Burlington House, London WIV 0NL. It is hoped to inform successful candidates by early April 1975.

# UNIVERSITY OF BRISTOL DEPARTMENT OF PATHOLOGY

# POSTDOCTORAL RESEARCH ASSOCIATE

A postdoctoral research associate is required to work in the Comparative Pathology Laboratory, School of Veterinary Science, Langford, Bristol, in collaboration with Dr D. J. Etherington of the adjoining Meat Research Institute (A.R.C.) on the purification, biochemical properties and mode oction of a lysosomal collangenolytic cathespin. This is a funded post, supported by a grant, initially for three years, from the Arthritis and Rheumatism Council, with a salary on the scale £2,580 to £2,931 per annum.

Applications in writing giving details of age,

Applications in writing, giving details of age, qualifications and research experience, plus the names of two referees, to Professor I. A. Silver, Pathology Department, Medical School, University Walk, Bristol BS8 1TD. (2014)

# Anglo-Australian Telescope Board

The Anglo-Australian Telescope Board invites applications for vacant positions at its scientific headquarters operations, currently located in Epping, near Sydney. In addition to its Epping site, the Board operates a 3.9 metre optical Telescope in the Warrumbungle mountains near Coonabarabran, about 200 miles north-west of Sydney. The Telescope is maintained by a resident site organisation but from time to time it will be necessary

# Assistant Librarian or Librarian Class 1

Duties will include cataloguing scientific and technical publications; maintaining the periodical subscriptions; ordering books, etc. Applicants should have a University degree (preferably in science) or attained Associateship of the Library Association or passed one of the professional examinations of the Library Association.

Salary Range \$A 5290 to 9262

# **Assistant Photographer**

Duties will include testing of astronomical plates; assisting the astronomical staff; preparing prints and slides from astronomical negatives and overseeing the purchasing and preparation of photographic chemicals and materials. Applicants should have diversified photographic experience, although experience in scientific laboratories would be valuable.

Salary Range \$A 7756 to 11360

#### **Tool Room Machinist**

The successful applicant will assist the scientific and technical staff in maintaining and instrumenting the new Anglo-Australian Telescope. Experience in working with a scientific group in developing new equipment will be valuable. Applicants should have had extensive experience on all types of machine tools. Salary Range \$A 6790 to 8696

### **Electronics Technician**

The successful applicant will assist the scientific and technical staff in maintaining and instrumenting the new Anglo-Australian Telescope. Applicants should have an ONC in Electrical Engineering, or an equivalent qualification, and have served an apprenticeship followed by at least 3 years' experience in a variety of electronic fields, but with an emphasis on digital electronics.

Salary Range \$A 7756 to 10495

for headquarters personnel to travel to site for a few days to assist the site organisation. The tenure of these appointments is for an indefinite period and carries superannuation benefits. Appointees recruited to permanent positions from outside Sydney will have their fares to Sydney (and those of their dependants) paid by the AAT Board. The vacant positions include:—

### **Design Draughtsman**

The successful applicant will work with the AAT scientific and engineering staff in the preparation of designs and drawings for the AAT. Applicants should have an ONC or an equivalent qualification and have served an apprenticeship or had equivalent training for at least 3 years, together with at least one year's drafting experience. Experience in working with other scientific organisations would be valuable.

Salary Range \$A 7756 to 10495

### Mechanical/Optical Engineer

The successful applicant will be expected to assist the scientific staff of the AAT in the design and construction of new instruments for the AAT. Many of these instrument will be novel, experimental devices and will require a high degree of engineering ingenuity for their successful development. In addition the successful applicant will be expected to support the staff in maintaining the effectiveness of the Telescope.

Applicants should posses a degree in engineering or have passed the Council of Engineering Institutions Part 2 examination in appropriate subjects or should possess an equivalent academic qualification, together with extensive engineering design and drawing office experience.

Salary Range \$A 10465 to 14049

### **Electronics Engineer**

The successful applicant will be expected to assist the scientific staff of the AAT in the design and construction of new instruments for the AAT. Many of these instruments will be novel, experimental devices and will require a high degree of engineering ingenuity for their successful development. In addition, the engineering staff is expected to support the site staff in maintaining the effectiveness of the Telescope.

Applicants should possess a degree in electronic engineering or physics or have passed the Council of Engineering Institutions Part 2 examination in appropriate subjects or should possess an equivalent academic qualification, together with several years' experience in circuit design, digital logic and computer operations.

Salary Range \$A 7000 to 14049

Applications, giving details of qualifications and experience and the names and addresses of 3 referees, should be made by letter to:---

The Executive Officer, Anglo-Australian Telescope Board c/o Department of Science, PO Box 449, Woden, ACT 2606, Australia by 13 December, 1974

#### FIELD STUDIES COUNCIL DEPUTY WARDEN

at Juniper Hall Field Centre, near Dorking. Good degree in biological science, educational qualifications. At least two years professional teaching experience including fieldwork. Wide environmental interests, but special knowledge of botany an asset.

interests, but special knowledge of botany an asset. Besides teaching, duties include administration (staff, student supervision, programme planning, equipment, etc.) in consultation with Warden as his second in command. Research opportunities. Salary £1,800 by £75 to £2,025 plus free board and lodging. Appointment January 1975, closing date for applications November 30, 1974. Further details and application forms from the Director, Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. (2013)

#### YALE UNIVERSITY REPRODUCTIVE BIOLOGY

Department of Obstetrics and Gynaecology Department of Obstetrics and Gynaecology seeks a senior experienced investigator to lead reorganisation and direction of departmental programme in reproductive biology. New laboratory and animal facilities available. Strong clinical endocrinology, receptor pharmacology, electron microscopy and in witro fertilisation elements already functioning. Appointment at Associate Professorship level (university funded) with joint appointment of appropriate individual in basic science departments with access to graduate students, and participation in university-wide reproductive biology centre. In accord with Yale University's Affirmative Action Programme, the search committee welcomes women and minority group candidates.

Applicants should submit curriculum vitae and

Applicants should submit curriculum vitae and bibliography to Nathan Kase, M.D., Chairman of Search Committee, Department of Obstetries and Gynaecology, Yale University School of Medicine, 333 Cedar Street, New Haven, Connecticut 06510.

#### UNIVERSITY OF THE WITWATERSRAND Johannesburg, South Africa

#### LECTURER IN MICROBIOLOGY

Applications are invited for the above post in the Department of Botany and Microbiology. A special knowledge in microbial industrial applications or microbial metabolism would be an advantage, but not essential for the position offered

The two-year degree course, which is in the process of development, caters for both pure and applied aspects of microbiology.

The salary scale attached to the post is R6,300 by 360 to R 9,180 (£1=R1.62), and the initial salary will be determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities and a housing subsidy (if eligible).

housing subsidy (if eligible).

Intending applicants should obtain the information sheet relating to this post. The policy of the University is not to discriminate in the appointment of staff or the selection of students on the ground of sex, religion, race, colour or national origin. Further particulars relating to this policy and the extent to which it can be implemented in practice, are included in the information sheet, which should be obtained from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than January 10, 1975, U.K. applicants may obtain the information sheet relating to this post from the London Representative, University of the Witwatersrand, 278 High Holborn, London WCI. (2008)

#### MEDICAL RESEARCH COUNCIL

#### SCIENCE GRADUATE

#### FOR BIOCHEMISTRY DIVISION

The National Institute for Medical Research has a vacancy for the post of JUNIOR TECHNICAL OFFICER in the Biochemistry Division. The research being carried out is concerned with the preparation and characterisation of mammalian cell membranes. As a theoretical understanding of the research would be useful, applicants should preferably have graduated in biochemistry or have studied a biological subsidiary. Salary scale from £1,875 p.a. plus £167 p.a. threshold agreement (maximum £2,718 plus £167 p.a.). To obtain application forms please write quoting ref: JTO/BM to Mrs M. Y. Jim, Assistant Personnel Officer, N.I.M.R., The Ridgeway, Mill Hill NW7 1AA. Tel: 01-959 3666. (2018)

#### **GRIFFITH UNIVERSITY** Brisbane, Australia

#### LECTURESHIP-EXPERIMENTAL PHYSICS SCHOOL OF SCIENCE

Griffith University will admit its first undergraduates in March 1975 and is committed to interdisciplinary teaching methods. The appointee, in addition to first year teaching duties, will have a particular responsibility, in collaboration with existing staff, for the development of second year courses. The research interests of the School are in solid state physics, chemistry and biochemistry. The appointee should be prepared to be associated with interdisciplinary research projects, in addition to pursuing his own research interests. Applications are invited from men and women for this position, which closes on **December 16**, 1974.

The appointment will be from March 1, 1975, or as soon thereafter as possible, at a salary in the range \$A9,002 to \$12,352 (currently under review). This appointment will be made in the lower half of the range.

Further information, conditions of appointment and details of the method of application can be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF. (2010)

#### JAMES COOK UNIVERSITY OF NORTH QUEENSLAND TECHNICAL OFFICER SCHOOL OF BIOLOGICAL SCIENCES

The successful applicant will be responsible for the general management and maintenance of the equipment and supplies of the Departments of Botany, Marine Biology and Zoology as well as for the training and supervision of all the technical staff of the Sobool. Applicants should be over the age of 25 years, have a technological diploma or equivalent and at least five years' experience in a biological laboratory, preferably with some of this time in an administrative capacity. An interest in Marine Biology research would be an advantage.

Marine Biology research would be an advantage.

Sallary ranges are: Technical Officer Grade 1—
\$A319.10 to \$344.40 per fortnight (\$A8,323 to \$8,983 p.a.); Technical Officer Grade 11—\$A353.20 to \$379.60 per fortnight (\$A9,213 to \$9,903 p.a.).

A locality allowance of \$A142 p.a. for a married male or \$A71 p.a. for a single appointee also payable. Conditions of appointment include F.S.S.U. superannuation, invalid pension scheme, housing assistance, study leave and allowance for travel and removal expenses on appointment.

Further details and application forms obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH 0PF.

Applications close December 6, 1974. (2011)

#### Department of Health and Social Security, London

■ In Hospital Scientific and Technical Services Unit ■ Assist in the formulation of policies in the laboratory science field of microbiology, haemotology and clinical chemistry.

☐ 1st/2nd hons degree or equivalent in appropriate scientific subject ☐ 4 years' post-graduate experience, including some in a hospital laboratory  $\square$  Age under 32  $\square$  Appointment as Senior Scientific Officer (around £3550 to over £4800)  $\square$  Ref: SB/3/K.

Application forms (for return by 13 December 1974), from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 (or, for 24 hour answering service, London 01-839 1992).

#### Department of the Environment Central Water Planning Unit, Reading

# Chemists

■ In Water Quality Division ■ Appraise capacities, tolerances and failure rates of water supply treatment and effluent treatment methods Assess suitability of water sources for potable and industrial supplies ■ Relate water quality data to methods of effluent treatment, land use practices and reservoir operations ■ Evaluate implications of alternative strategies in the context of river water quality, water treatment and effluent treatment. 

Possibly of collaboration with water systems analysis on the development of water quality models.

☐ 1st/2nd hons degree or equivalent in Chemistry or corporate membership of an appropriate institution  $\square$  Experience of either water supply chemistry, effluent water chemistry or river water chemistry desirable  $\square$  Age under 32  $\square$ Appointment as Senior Scientific Officer (over £3300 to around £4600) or Higher Scientific Officer (£2600 to over £3500) according to age and experience Ref: SA/7/HF.

☐ Application forms (for return by 13 December 1974), from Department of the Environment, Room 446, Lambeth Bridge House, Albert Embankment, London SE1. Telephone 01-735 7611 ext. 1469 or 2094.

#### UNIVERSITY OF WESTERN AUSTRALIA Perth

PHYSIOLOGY

Applications are invited for appointment as LECTURER or SENIOR LECTURER

LECTURER or SENIOR LECTURER
in the Department of Physiology. Applicants
interested in joining the auditory physiology and
biophysics group would be particularly welcome.
The laboratory is exceptionally well equipped for
investigating all functions of the peripheral
auditory system and could also provide facilities
for study of the central auditory pathway. The
current salary ranges are: Lecturer—\$A9,002 to
\$A12,352 p.a.; Senior Lecturer—\$A9,002 to
\$A14,724 p.a. Benefits include superannuation
similar to F.S.S.U. fares to Perth for appointee
and dependent family, removal allowance, study
leave and long service leave and housing loan
scheme. Further information may be obtained
from the Staffing Officer.

Applications in duplicate stating full personal
particulars, qualifications and experience should
reach the Staffing Officer, University of Western
Australia, Nedlands, Western Australia 6009, by
January 11, 1975. Candidates should request three
referees to write immediately to the Staffing
Officer. (2009)

#### UNIVERSITY OF THE WITWATERSRAND Johannesburg, South Africa

CHAIR OF BOTANY

CHAIR OF BOTANY

Applications are invited for an additional Chair of Botany. Preference will be given to persons who have research interests in one of the modern aspects of the plant sciences.

The salary attached to the post is in the range R10,800 by 450 to R12,600 by 600 to R13,800 (£1=R1.62), the initial salary to be determined according to qualifications and experience.

Intending applicants should obtain the information sheet relating to this post. The policy of the University is not to discriminate in the appointment of staff or the selection of students on the ground of sex, religion, race, colour or national origin. Further particulars relating to this policy and the extent to which it can be implemented in practice, are included in the information sheet, which should be obtained from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than January 6, 1975. U.K. applicants may obtain the information sheet relating to this post from the London Representative, University of the Witwatersrand, 278 Tigh Holborn, London WC1.

FIELD STUDIES COUNCIL TUTOR

TUTOR
in Geography or Geology at Juniper Hall Field Centre, Dorking. Single, good degree, emphasis on physical aspects. Educational qualifications desirable. Research opportunities. Salary £1,200 by £75 of £1,330 plus free board and lodging. Appointment January 1975. Closing date for applications November 30, 1974. Further details and application forms from the Director, Field Studies Council. Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. (2012) (2012)

#### UNIVERSITY OF LEEDS DEPARTMENT OF EXPERIMENTAL PATHOLOGY AND CANCER RESEARCH **TECHNICIAN**

required to assist a group engaged in developing short-term tests for chemical carcinogens. Candidates should have a background in microbiology, biochemistry, or mammalian cell culture. The position, which is funded by The M.R.C., is for 3 years and the salary will start at the appropriate point on the grade 3 scale (£1,650 to £1,920, plus threshold payments).

Applications in writing giving details of career should be sent to Dr R. C. Garner, University of Leeds, Leeds LS2 9JT. (2016)

# **Biologist**

### for Environmental work about £4500

BP Chemicals International require a biologist to join their environmental group based in Central London.

This group is responsible for providing advice to management on all environmental matters and ensuring that all necessary information on this subject is available to assist decision making. Important parts of this work are monitoring the effect of company activities in areas close to plants and considering biological methods of treating certain wastes. It is a small group in which members need to be able to operate independently in discussions at senior level both within the company and with outside bodies.

Candidates must have a degree in a biological science followed by a number of years' industrial experience, which has included work of a biological nature. The successful applicant will need to become acquainted with the biological aspects of air and water quality standards and with the major processes operated by the company.

Starting salary will be around £4500 including Inner London Allowance. In addition there is a threshold payment of £166. Career development prospects within the BP group of companies are excellent and the conditions of employment include a non-contributory pension, 4 weeks' holiday and an excellent subsidised restaurant.

Please write or telephone for an application form to: E. P..A. Norman, BP Chemicals International Ltd., Devonshire House, Piccadilly, London W1X 6AY. Tel: 01-629 8867, ext. 76.

**BPchemicals** 

#### THE DEPARTMENT OF PSYCHOLOGY PRINCETON UNIVERSITY

anticipates several openings for the 1975–76 academic year. One is at the Full Professor level in social psychology, where we seek an addition to our ongoing programme in social psychology. The other(s) at the Assistant Professor level are in ne other(s) at the Assistant Professor level are in general experimental psychology, with concentration in animal behaviour, developmental and comparative psychology, or personality research. These latter anticipated openings are not rigidly tied to any specific area of expertise. Sheer excellence in research and teaching will override area-of-interest considerations.

Nominations and applications should be sent to the Chairman, Department of Psychology, Green Hall, Princeton University, Princeton, New Jersey 08540. We are an equal opportunity employer with a vigorous affirmative action programme. (2022)

#### UNIVERSITY OF NAIROBI Kenya

Applications are invited for the following posts in the DEPARTMENT OF ANIMAL PRODUCTION:—

DUCTION:—

1. ASSOCIATE PROFESSOR. Applicants, who must have a Ph.D. in either Animal Nutrition, Genetics and Breeding, or Ecology and Management, should also possess a good general background in the other branches of Animal Production. They must have done several years of relevant university teaching and have experience in directing postgraduate students. A knowledge of production systems in the tropics, preferably in East Africa will be an advantage but not essential.

of production systems in the tropics, preferably in East Africa will be an advantage but not essential.

2. THREE SENIOR LECTURERS. Applicants should have a good first degree in either Veterinary Medicine or Agriculture and preferably a Ph.D. Candidates holding lower qualifications (not less than an M.Sc.) will only be considered if they have several years research and teaching experience at university level, in either Animal Feeding, Management or Breeding.

3. LECTURER IN ANIMAL BREEDING. Applicants should have a good first degree in either Veterinary Medicine or Agriculture and at least an M.Sc. in the field of Animal Breeding. Experience in teaching at university level will not be necessary for holders of a Ph.D. in this field. Salary scales: Associate Professor K£3,036 to K£3,564 p.s. Senior Lecturer K£2,256 to K£3,036 p.a. Lecturer K£1,500 to K£2,580 p.a. (K£=£1.19 sterling). The British Government may supplement salaries in range £900 to £1,860 p.a. (sterling) for single appointees (normally free of all tax), and provide children's education allowances and holiday visit passages, FS.S.U. Family passages; various allowances. Detailed applications (2 copies) including a curriculum vitae and naming 3 referes, should be sent by airmail, not later than December 30, 1974, to the Registrar, University of Nairobi, PO Box 30197, Nairobi, Kenya. Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London WIP ODT. Further particulars may be obtained from either address. (2026)

#### FELLOWSHIPS AND **STUDENTSHIPS**

#### RHEUMATOLOGY CLINICAL TRAINING FELLOWSHIP

Division of Rheumatology of the Department of Medicine, S.U.N.Y. is accepting applications for January 1, 1975 appointment. Inter-disciplinary rheumatic study involving the departments of Pathology, Medicine and Bio-Medical Engineering has been established offering major opportunities in research and clinical activities. E.C.F.M.G. required. Starting salary \$18,000 per year. Applications should be sent to Leonard E. Meiselas, M.D., Professor of Medicine, Project Director, School of Medicine, Health Sciences Center, State University of New York at Stony Brook, Stony Brook New York 11794, An Equal Opportunity/Affirmative Action Employer. (1956)

#### UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSICS

DEPARTMENT OF PHYSICS

An S.R.C./C.A.S.E. studentship is available for studies in the fields of ionospheric physics and radiowave propagation leading to a higher degree. The project is related to current research in the field of high frequency communications and is sponsored by a Government Laboratory.

Applications are invited from graduates in physics, mathematics or electrical engineering and should be sent to Dr. T. B. Jones, Department of Physics, University of Leicester, Leicester LEI 7RH. (1964)

#### THE ROYAL SOCIETY

John Murray Travelling Studentship in Oceanography and Limnology 1975

Applications are invited for the above Student-Applications are invited for the above Studentship, open to male or female graduates under the age of 35, for the encouragement of travel and work in oceanography or limnology. This award, which may be held for periods from three months to one year, will in 1975 be up to £1,000, adjusted according to qualifications and place and duration of research. Applications are especially invited from workers in oceanography and immology, as well as in zoology, botany, geology, mathematics and physics, and it will be permitted to hold the award while receiving a salary from a regular appointment. regular appointment.

Applications receivable by December 15, 1974, should be made on forms obtainable from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. (1952)

#### UNIVERSITY OF ABERDEEN RESEARCH FELLOW IN ENGINEERING SCIENCE

Applications are invited for the above post, to work with Professor J. F. Eastham on linear induction motors.

The post is financed by the S.R.C. and is tenable for three years. Salary within the range £2,118 to £2,412 plus threshold payments.

Further particulars from The Secretary The University, Aberdeen, with whom applications (3 copies) should be lodged by December 14, 1974.

(1981)

#### POSTDOCTORAL RESEARCH **FELLOWSHIP**

is available for working on the chemical basis of single protein-RNA interactions in bacterial ribosomes. Previous research on nucleic acid modification or sequence determination, or in the fields of physical chemical or X-ray crystallographic studies on proteins or RNA is preferred.

The Fellowship commences on about April 1, 1975 and continues for about two years. Knowledge of German is not essential. The salary is approximately £5,000 per year and is taxable.

Applications should be made in writing, with details of previous research experience and current interests, to Dr R. A. Garrett, Max-Planck-Institut für Molekulare Genetik, Ihnestrasse 63/73, 1 Berlin 33 (West). (1974)

#### UNIVERSITY OF READING PLANT SCIENCE LABORATORIES DEPARTMENT OF BOTANY

#### S.R.C./C.A.S.E. STUDENTSHIP IN **PHYTOCHEMISTRY**

Applications are invited from Honours Graduates in Organic Chemistry, Biochemistry or Botany to work on "Comparative Aspects of Phytoalexin production in the family Leguminosae" in association with I.C.I. Plant Protection Ltd., Jealott's Hill Research Station, Bracknell, Berks.

The studentship is available immediately for a period of up to three years.

Application with a curriculum vitae and the names of two referees should be sent to:

Dr J. B. Harborne, Phytochemical Unit, Plant Science Labs., University of Reading, Whiteknights, Reading RG6 2AS

(1990)

#### UNIVERSITY OF DUNDEE

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

#### POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from candidates with experience of biochemical techniques for a postdoctoral research fellowship in the above department based at Ninewells Hospital and Medical School, Dundee. The appointment which will be for 3 years will involve work in a research project on the effect of drugs on red blood cells and the protective effects of the enzyme systems. The initial salary will be £2,118 per annum.

annum.
Further information can be obtained from Dr. G. R. Tudhope at the Department of Pharmacology and Therapeutics, Ninewells Hospital Dundee, DD2 1UD.
Applications, together with a curriculum vitae and the names of two referees, should be sent to The Secretary, The University. Dundee, DD1 4HN, by December 13, 1974.

(1968)

#### UNIVERSITY OF EDINBURGH RESEARCH ASSISTANT

required by the DEPARTMENT OF MOLECULAR BIOLOGY to join a research team studying protein synthesis in relation to cell division in bacteria. Applicants should possess cither H.N.C., A.I.M.L.T. or B.Sc. (Hon) in appropriate subjects.

The post is grant supported for three years in the first instance with a possibility of renewal thereafter. Salary will be on scale £2,247 to £2,628 or £2,439 to £2,895.

Applications, quoting the post reference number (A085), should be addressed to the Personnel Officer, University of Edinburgh, 63 South Bridge, Edinburgh EH1 ILS. Tel 031-667 1011 extn. 4446. (2015)

#### POSTDOCTORAL FELLOWSHIPS DEPARTMENT OF PHYSICS

UNIVERSITY OF WATERLOO Waterloo, Ontario, Canada

Applications are invited for postdoctoral research fellowships in physics.

Fellowships carry a stipend of \$9,600 per annum (after March 31, 1975) which is subject to Canadian income tax. The awards are tenable for a period of one year with a possible renewal for a second

Research areas include: Astronomy and Astrophysics (applicants in this area should be interested in teaching and in observational galactic structure of Southern Milky Way and related topics), Atomic and Molecular Physics, Biophysics, Crystallography, Electron Microscopy (thin crystal defects and interfacial structures), Ellipsometry, Condensed Inert Gas Properties, Laser Physics, Microwave Physics, Nuclear Magnetic Resonance, Solid State Physics (insulators, motals, non-linear dielectrics, and semiconductors), Statistical Mechanics, Superfluidity, Superconductivity, and Ultrasonics. Closing date for applications is March 15, 1975.

For further information write to:

Dr D. E. Brodie
Acting Chairman
Department of Physics
University of Waterloo
Waterloo, Ontario, Canada N2L 3G1
(2021)

#### ALCOHOLISM M.C.A. RESEARCH FELLOWSHIP

The Council offers a Fellowship of 2 or 3 years to a medically or scientifically qualified worker for research into the cause, detection or prevention of alcohol dependence. The financial support will be adjusted to the experience of the worker and the demands of the proposed research. Full information from: The Executive Director, The Medical Council on Alcoholism, 8 Bourdon Street, London WIX 9HY. (1864)

#### BROWNE RESEARCH FUND MAURICE HILL RESEARCH FUND Grants 1975

The Council of the Royal Society invites applications from qualified research workers for personal grants

- cations from qualified research workers for personal grants

  (a) from the Browne Research Fund, for research in marine biology at a marine biological laboratory or elsewhere. Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end.

  (b) from the Maurice Hill Research Fund (established in memory of the late Dr. M. Hill, F.R.S., for the encouragement of research in physical oceanography and marine geophysics) for research at sea and/or in the laboratory in physical and chemical oceanography, marine geophysics and geology.

  Grants may be used for periods up to one year, and are made on the understanding that university or other posts held by applicants will meanwhile be kept open for them.

  In 1975 the amounts available will be about £4,000 from the Browne Research Fund and £2,500 from the Maurice Hill Research Fund.

  Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by December 15, 1974. (1951)

#### FOR SALE AND WANTED

#### SOFT LASER SCANNING DENSITOMETER

New for scanning Isoelectric Focusing in tube or plate form. High 31 res-olution. Also for emission plates, X-ray film, TLC and clinical electro-TLĆ

phoresis. Recorder and integrator included. Mail samples for free scanning.

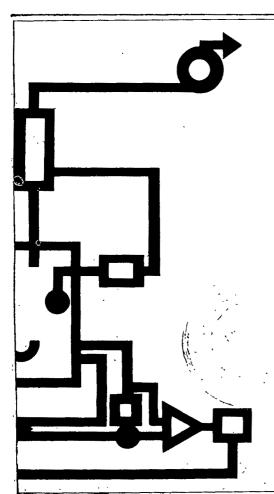

#### **ALSO**

Single Hollow Fiber Concentrator for concentrating urine, CFS and other fluids. 2 ml - 20 fold in 25 seconds, 200 ml to 1 ml in 45 minutes. Reusable. Anal. Chem. 46:477,1974.

### **Gas Analysis Instrumentation**

Anthony Verdin

The detection and analysis of gases and vapours has become essential in many areas of modern life; noticeably industrial safety and control of the environment. As a result a whole class of physio-chemical methods has come into existence. The author draws on his fourteen years of experience in the field to supply the only wide-ranging view of all types of equipment presently available. Both academics and industrialists will find it indispensable.

#### Electrical Breakdown in Gases

Edited by J. A. Rees

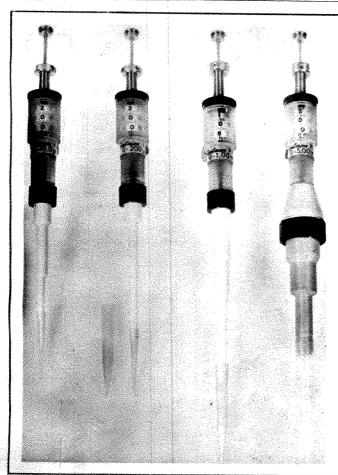

The electrical breakdown of gases has been studied in the laboratory since before the start of this century and it is sixty years since Sir J. S. Townsend wrote his monograph The Theory and Ionisation of Cases by Collision. In that time the subject has been widely studied and a great deal of progress has been made in understanding many aspects of the problem. J. A. Rees has selected the major papers in this field and has linked them with comments and an introduction. Reprinted from the the original sources, the papers together provide a unique introduction to the ionisation of gases.

#### Introduction to Space Charge **Electron Optics**

G. A. Nagy and M. Szilagyi

This introduction to space charge electron optics is an updated translation of an original Hungarian publication which presents to the West for the first time a comprehensive survey of the vast work carried out in this field in the USSR and Eastern Europe. It is however more than just a symmary of literature as it also contains the solution of many problems and so points the way to future developments.

# **Precision Instruments**

# Polarimeter Model A

This instrument gives the highest degree of accuracy with divided circle on glass reading to 0.01 degree.

Circle centre on ball bearings · Easily removable trough · Divided drum replacing verniers · Stationary observation telescope · Circle reader enlarging image of scale · Slow motion adjustment always in action · Suitable, with additions, for measurement of rotatory dispersion.

This polarimeter has been supplied in large numbers both in this country and abroad, and has always been acclaimed as being of advanced design and workmanship. Please ask for particulars "N".

We now have capacity for aluminising certain types of mirrors, at short notice.

Pion advanced biochemistry series

#### **Biochemical Reactors**

B. Atkinson August 1974, 267 pp., £5.00/\$13.00

0.82086.042.3

The pressure created by demands for new products and processes necessitate rapid changes in the biochemical process industries. Continuous processes must replace batch processes, but require much higher levels of biochemical, microbiological and engineering knowledge. In this work the author, while dealing with fermenter and reactor design, develops the algebra necessary to describe the operation of "ideal" fermenters, where the fluid mechanics and the relations between substrate uptake and product formation are relatively simple.

### Space-Time Concepts in Urban and Regional Models

edited by E. L. Cripps August 1974, 237 pp., £4.00/\$10.25

0.85086.044.X

The papers in this volume, presented at the 1972 Annual Conference of the Regional Science Association, deal with aspects of the spatial organisation of cities and regions, and a considerable number of them deal with the development of spatial systems in time. The papers are organised into five parts; the notion of space-time development in regional science, developments in more conventional modes of regional economies, abstract models relying mostly on theory and analytical methods for their solution, the development of more operational models and the methodology of urban design and planning.

### **Introduction to Noise Analysis**

R. W. Harris and T. L. Ledwidge September 1974, 102 pp., £2.50/\$6:50

0.85086.041.5

As on-line machines capable of rapidly analysing such statistical parameters as probability functions, spectral composition and correlation functions become available to practicing engineers and scientists, the application of no se techniques will increase. It was with this class of non-specialists in mind that this book was written. Noise analysis is not offered as a universal technique capable of solving all problems, but rather as an adjunct to the classical methods already well known and tried.

Pion advanced biochemistry series

### **Brain Function and Macromolecular Synthesis**

August 1974, 156 pp., £3.50/\$9.00

0.85086.043.1

In this book, Dr. Jacoubek brings together for the first time the vast range of observations relating brain function to the synthesis of macromolecules, and provides a critical interpretation of these observations in the light both of theoretical and methodical considerations. While placing emphasis on the difficulties met in measuring changes in the rates of macromolecular synthesis in nerve cells, he underlines the part played by stress reactions that are involved in a number of so-called learning

# handbook of genetics

edited by Robert C. King

This basic handbook, highlighting classical studies, deals with the biology of many species that are frequently used by geneticists. Leading specialists offer an introduction to the morphology, life cycles, reproductive behavior, and culture methods for geneticallyknown species and provide up-to-date data on genetic and cytological maps, mitotic karyotypes, and haploid DNA values.

#### Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in Nature. A limit of 300 words is placed on contributions.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e<sup>a</sup> if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. See any contemporary Nature for style, but note:

- (i) To refer to several references by the same author at once, only one reference number need be given.
  - (ii) Cite first and last pages.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. We are always glad to see artwork for possible use on the cover, whether or not it is associated with a manuscript, but cannot guarantee the return of material.

Obituary	429
Announcements	430

It's your journal

"We would be happy to publish your letter if you could cut it in length by about 30%."

"We could publish your communication at letter length of about 1,000 words but not as a 3,000-word article."

"We regret it is almost impossible to publish an article of 6,000 words."

"We regret that your letter seemed too specialised for a journal aiming at a wide readership."

These are four of the types of letter that we don't like sending any more than you like receiving. For some years Nature has been publishing communications in the form of commissioned articles or reviews, research articles and letters. Looking back further, however, one sees that this format has only been reached by an evolutionary process; indeed the early issues of Nature contained an extraordinary diversity of material which the editor did little to segregate. Quarrels, opinions, anagrams and observations of atmospheric phenomena rubbed shoulders with announcements of scientific progress. Presumably those with a serious message did not have as great an objection as present-day scientists would to their scientific wheat sitting amongst anecdotal chaff—probably because they knew that next time they wrote it was as likely as not to be an anecdote that they sent.

In the past year we have tried to continue to evolve. A section has been started in which scientists can raise, briefly, points relating to earlier papers in Nature. (Though not too much earlier—about a year after publication we have to assume that ideas floated in our columns are starting to go through the normal refining process in the specialised literature and need no corrective action from us.) Further we occasionally take a more general communication and publish it in News and Views, particularly when it raises a controversial point of broad interest. Finally, we try to include after the leader a piece concerned with broader issues of science—policy, politics, method and so on. As often as not this will have been submitted originally as a letter. We are always pleased to see potential material both for News and Views and for the 'broader issues' pages, although the criteria by which we accept or decline have to be fairly subjective.

Although we have some instinct for what should go into these sections of the journal, and we expect that referees will have an instinct for the accuracy and general significance of the technical content of the papers communicated to us, we have a very limited ability to tell whether our present division into articles and letters and our present prescribed maximum lengths are in tune with authors' and readers' needs. Of course, we have (quite conflicting) opinions in the *Nature* office, and, of course, we do discuss the matter on occasions with scientists. But we lack any sort of market-place response. The number of subscribers who will cancel their subscription simply

because they find articles too specialised or letters too telegraphic is probably few. Again, it is difficult to judge whether a particular paper goes to another journal because it could not be condensed to a thousand words, because of the delay time in publication (though watch ours drop) or for any of half a dozen other reasons.

Because of all this, we take the perhaps foolish step of inviting opinions on how the medium could change the better to proclaim the message. There are some constraints. The upper limit of 3,000 words and six displayed items could not be revised upwards, simply because very long articles restrict the spread of interests in any particular issue and cut the acceptance rate for other manuscripts. Further, any policy by which the average length of letters is increased necessarily means that fewer can be published, as the number of pages that we can produce is unlikely to grow under present economic conditions. We do not, however, believe that the present acceptance rate of about 35% is an unalterable number.

Granted this, should we publish less or more papers of article length? And should we require that an article be particularly accessible to the general readership or would this destroy an important means of scientific communication? Should the distinction between articles and letters (a frequent bone of contention amongst authors cunningly submitting an 1,800-word paper) be abolished? Should the length limit for letters be raised—or even lowered?

We do make two pleas. First, that many authors have an ability to write to the limit whatever it may be and do not see it as a challenge to say in 600 words what might be expanded to 1,000. We shall continue to try to keep papers short and to cut out material which would be appropriate to a specialised journal but which gets in the way of the reader with limited time attempting to find out if there is anything in it for him. It is undoubtedly true that the shorter the paper the better the chance it has of being read widely.

Second, many papers have a depressing opacity which could easily have been alleviated before they were sent. If more authors would try out manuscripts on colleagues in different disciplines before submitting and would attempt to make the first paragraph into a crystal-clear description of what the paper is about rather than what other people's papers have been about, Nature would be an easier journal to read.

M. MARTIN, a French telegraphic engineer, has invented as engine for recording votes. The contrivance has been designed on the principle of the sonnettes electriques, and is exhibited in a shop in the Place Dauphine. The peculiarity is that the votes are registered and their total reckoned automatically. The invention is attracting public notice, as it is expected that the Versailles representatives will have an immense number of votes to register during the next session.

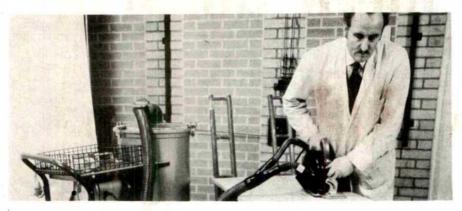

From Nature, 11, 94, December 3, 1874.

### For those in peril: 3 - not only on the factory floor

Dr D. R. Bowes of the Department of Geology at the University of Glasgow points out that not only workers but the general public could be at risk from asbestos and other mineral dusts in the environment and that more research is needed on this particular topic.

THE discussion by Peter J. Smith of occupational exposure to asbestos (Nature, October 18) highlights a major obstacle to a concerted effort by the scientific community in the field of the relationship of mineral and rock dusts to human disease, namely the apparent lack of awareness of the problems by many mineralogists, geochemists and geologists and hence of the neglect of their expertise. Some are involved but, however significant their contributions may be, it has been a relatively small group of the medical profession who has pinpointed the vital role of mineralogy and allied fields as well as demonstrated the health hazards associated with the inhalation of mineral and rock dusts. Much of the recent direction of public attention to the matter stems from an articulate few who see not only the value of scientific research to community health, but also to social and legislative action. They have been supported, particularly in the United States in recent years, by active collaboration with physical scientists, which has not only contributed to medicine but has opened frontiers in the physical sciences. In Britain it is more than 40 years since an industrial survey showed the high prevalence of asbestosis in asbestos factory textile workers, and that came nearly a quarter of a century after Parliament was first notified, in 1906, about fatal pulmonary asbestosis amongst asbestos workers. With such a passage of time, and its implications for human disease and suffering, the focusing of attention of physical scientists on occupational exposure to asbestos, and to the many other mineral and rock dust materials associated with mining, milling and manufacturing industry, is a matter of urgency.

Urgent attention should also be given to potential health hazards concomitant with environmental exposure. The incidence of pleural calcification resulting from environmental exposure in the neighbourhood of an asbestos mine or mill, or of pleural mesothelioma, without occupational exposure, in areas where there is asbestos in the local rocks, serves to illustrate that potential

Not the only one at risk

risk is not limited to occupationally exposed miners and industrial workers. The 1971 Report of the National Institute of Occupational Diseases, Johannesburg records that more than a third (of 210) of cases of mesothelioma were considered to be the result of environmental and not occupational exposure asbestos. This, together with evidence that asbestos greatly multiplies the already considerable lung cancer potential of cigarette smoking, suggests that combined scientific and medical research as a basis for legislative attention, as well as preventitive medicine, could have a significant effect on community health in at least some industrial areas.

The dimensions of any health hazard associated with air pollution caused by dusts, including asbestos, have yet to be defined and it is not proper to equate neighbourhood contamination with general community air pollution. The existence of levels of 10 to 50 ×10<sup>-9</sup> g m<sup>-3</sup> of chrysotile asbestos in the ambient air of places like New York City and the regularity with which asbestos fibrils are found at autopsy in the lungs of residents of New York and London, are probably indicators for other urban areas. The asbestos industry has an important responsibility for controlling the commercial and industrial sources of air pollution, but additional possible contributory factors, resulting from the action of the public at large, must not be passed by. These include dusts from asbestos brake drum linings and the mineralogy of decomposed lining material which could have a general effect as well as a localised one in the confined spaces of motor repair premises; inorganic particles in smoke from tobacco-that from some cigars is known to contain an inorganic fibrogen and that from cigarettes, is suspect in view of the relationship between cigarette smoking and lung cancer; and consumer talc products, which must represent one of the mineral dusts most inhaled and ingested by people of all ages in many households, with talc known to cause pneumoconiosis as the result of occupational exposure and to occur in nature together with some asbestiform minerals.

There are other factors to be considered in the control of environmental exposure to mineral and rock dusts through air pollution, and many other geological and mineralogical aspects to be assessed in the relationship between human health and the inhalation and ingestion of inorganic particles. And those instanced now under joint or separate investigation in the Environmental Science Laboratory, Mount Sinai Hospital, New York, and the Department of Geology, University of Glasgow show not only how in science something that is apparently obvious, with the benefit of hindsight, is not recognised until its possible effect on human welfare is appreciated, but also how in developing fields the availability of equipment that can help meet the new demands is vital. Identification of gaps in existing knowledge as suggested by Peter J. Smith is a useful next step but consideration of environmental exposure to mineral and rock dusts, as well as occupational exposure, is likely to reveal larger gaps than initially anticipated and to suggest that inclusion of matters affecting the health of the public at large will entail interdisciplinary endeavour on a considerable scale. Review and assessment alone will, however, not avert human suffering but could lead to frustration on the part of scientists and cynicism on the part of the general public if the will to accomplish is not matched by adequate provision of the tools needed, even if this means that certain other research topics, with less application to human suffering, are given reduced support.

# international news

THE European Science Foundation took a large step forward in Strasbourg last week with the election of officers and the creation of an executive council. Sir Brian Flowers, physicist and Rector of Imperial College, was elected President and the two Vice-Presidents are Professor O. Reverdin, a Greek scholar and Chairman of the Swiss Fond National and Dr P. Riis, a Danish physician. Secretary-General of the ESF will be Dr F. Schneider, at present Secretary-General to the Max-Planck Institut in Munich. Dr Schneider will work part-time in Strasbourg from January 1975 and eventually will be employed full-time by the foundation. Other officers will attend in Strasbourg for a couple of days a month on average, particularly for the meetings of the council of eighteen members. Britain has a second member on the council, Dr S. G. Owen of the Medical Research Council.

The ESF emerged as a concept when it became clear that there was considerable resistance to the idea of a pure research organisation being based on the EEC. Two of the most commonly heard arguments were that an ESF based on the Nine would be tied by the ponderous political procedures of Brussels and that learning knew no frontiers. Accordingly, and with the EEC's blessing, responsibility for the encouragement of European collaboration in the furtherance of research was passed on to an ESF comprised of representatives of almost all Western European countries, and there was a clear requirement that the body should have flexibility.

The word 'Science' in the title is interpreted in its broader European context of learning or knowledge. The 43 member organisations which sit in the assembly, the governing body of the ESF, thus comprise not only funding agencies such as research councils of the natural and medical sciences but also academies both of science and the humanities. The British seats in the assembly are occupied by the five research councils, the Royal Society and the British Academy.

The budget for the first year is to be 2.2 million French francs, most of which will go in administrative expenditures in Strasbourg; it is not envisaged that the ESF will become a funding agency. Rather it is seen as an enabling organisation, providing a forum for in-

# Flowers to head new European Science Foundation

ternational discussions on collaborative projects. There is to be no requirement that all members should agree on these projects; on occasions the ESF may simply serve as a template on which two or three research organisations in different countries can put together a scheme for which they have funds.

The success of ESF will clearly depend on its ability to show its useful-

Sir Brian Flowers

ness within the first year or two, and Sir Brian already has a list of projects to which the council will give early consideration. These are:—

Astronomy This is seen as a top priority as it is a natural field for multi-lateral collaboration and any consequent trimming of large national budgets on astronomy would be a big plus for the young ESF.

Archaeological techniques Clearly the archaeology of various parts of Europe differs widely, but techniques are much the same everywhere. The pooling of equipment and facilities could be the first step into the humanities for the ESF.

Comparative legal systems Getting to know how different countries work is going to be part of the European experience of the next ten or twenty years.

Social responsibility in biology Does this have a European dimension? ESF as yet does not know, but EMBO will be consulted early on the plasmid engineering issue.

Outside comment on large institutions Sir Brian would like to see ESF playing the same role in Europe as the National Academy of Sciences has done in the United States in providing informed comment and criticism on organisations such as ESRO. This is bound to be a fairly controversial proposal and he has already been presumed by some to be seeking to get at ESRO. Does ESF yet have the weight for this sort of operation?

Marine biology Ireland is particularly keen to advance in this field.

Science policy There is thought to be scope within the ESF for discussions on the development of a more pan-European approach to policy-making.

Supporters of the ESF are at pains to point out that one of the first jobs of the foundation is to establish good working relations with the already-existing European-wide science and medical research council collaborative efforts. Since it is these councils at a national level which have been, interalios, responsible for setting up the ESF this should not be a major difficulty.

In the longer run the ESF is seen as a body which national governments and international organisations will consult as a matter of course, if not as a legal necessity, on major matters of science and learning.

### New Astronomer Royal for Scotland

by John Gribbin

THE announcement that Dr V. C. Reddish is to succeed Professor H. Brück as Astronomer Royal for Scotland and Director of the Royal Observatory, Edinburgh (ROE) comes as no surprise to astronomers. Dr Reddish's new post is one of the two key jobs in the rebuilding of British optical astronomy (see Nature, 251, 456; 1974). The Royal Greenwich Observatory (RGO), under the Directorship of Professor F. G. Smith, will have responsibility for running the new Northern Hemisphere Observatory, whereas the ROE provides the base in the United Kingdom for the Science Research Council (SRC) team running the 48inch Schmidt Camera at Siding Spring and also plays a large part in the Anglo-Australian Telescope project. In addition, the ROE has the responsibility of setting up the 3.8-m infrared flux collector which is to be built in Hawaii with SRC funds (see Nature, 250, 617; 1974). So the responsibility for the hardware of what Professor Smith sees as a new 'Golden Age' of astronomy is divided evenly between Britain's two principal optical observatories.

Like Professor Smith at the RGO, Dr Reddish seems well qualified for the

task. His experience is rather more diverse that that of most academics, embracing 12 months in a brewery, three years in a bank and three years in the Royal Navy before he took his first degree. Since gaining his PhD as a member of University College, London, in 1954 Dr Reddish has been based in Edinburgh except for three years from 1959, which he spent at Jodrell Bank.

He says that those three years were

of great importance since they introduced him to the teamwork approach used by radio astronomers; with the electronic equipment attached to telescopes becoming ever more sophisticated there is now very little difference between the tasks of observers at radio, optical and other frequencies, and Dr Reddish realised from his experience at Jodrell Bank that modern astronomers would have to follow the same path of collaboration in order to get the best results out of their new instruments.

Since 1962 Dr Reddish has worked from time to time as a visitor at Hamburg, in the United States and in Australia; he was Project Officer for the construction of the United Kingdom Schmidt in Australia, and serves at present as one of three British members on the AAT Board. It is interesting that the future of British optical astronomy is largely in the hands of one man who has 'converted' from radio astronomy, and another who says that he learnt a great deal from his three years at Jodrell Bank. But divisions between observers today mean very little, and the real importance of both these appointments is that the men concerned have the proven administrative experience, as well as appropriate scientific pedigrees, to ensure that full advantage is taken of the opportunity now presented to British astronomy.

THE Soviet Mars mission of 1973-74 was only a partial success, with one intended satellite (Mars 4) and one landing craft (Mars 7) overshooting the planet. Results of the data from the more successful probes (Zemlya i Vselennaya, No. 5, 7-11; 1974), although scientifically stimulating, may well give certain embarrassment to Soviet politicians, for—in spite of their predilections for the colour—the red planet is, in fact, not quite as red as it has previously been painted.

According to the colour photographs received from the orbiting Mars 5 (and from the overshooting Mars 4), the craters in particular reveal significant variations of colour. Some of them exhibit a blue-green tint, contrasting sharply with the general orange background of the crater bottom. "If the correctness of the colour transmission is confirmed", says the report with some caution. "this may indicate that the bottoms of these craters are composed of rock different from that on the surface". Or (even more cautiously) "maybe, after all, there still exists vegetation on Mars?"

Passing quickly from these speculations, however, the report states a number of quantitative facts: the

### The not so red planet

from Vera Rich

argon content of the Martian atmosphere (according to mass spectroscopy measurements from Mars 6) has the very high value of  $35 \pm 10\%$ —a result at present inexplicable, although relative argon enrichment of the atmosphere as a result of the freezing of  $CO_2$  to form the polar caps has been postulated tentatively.

The amount of water vapour in the Martian atmosphere was found to be much higher than measured by Mars 3 and at places the amount of precipitated water reached 60-70 µm, some 3-5 times higher than the values obtained from the Mars 3 data of 2 years ago. The distribution of this moisture over the surface of the planet was found to be irregular. The joint Franco-Soviet polarimetry experiment gave results far lower than expected, the greatest polarisation (up to 10%—some 2-3 times less than that of the Moon)—being observed close to the northern extremity of the Argyre crater sea.

Infrared measurements gave surface temperatures very close to the theoretical models for highly fragmented rock; the highest temperature recorded being 272 K, corresponding to 1300 h local time. Correlation of surface temperature and relief has still not been observed.

Photography of the topographical features, apart from the curious problem of colour, has produced interesting results. With the high resolution used (down to tenths of a kilometre), the existence of two forms of crater was established: large craters having a flat bottom and slopes considerably affected by wind erosion, and small cup-shaped craters.

For a mission only partially successful in its hardware, the Soviet Mars survey of 1973-74 has not been unrewarding. Perhaps, however, the most significant data recorded are those from the analysis of the phase variation of the radio signals from the probes. From this it has been estimated that the electron concentration in the Martian ionosphere is  $6 \times 10^3$  electrons per centimetre at night and 1.5 × 105 electrons per centimetre by day. It seems likely that on the basis of these figures, future Mars probes will use wavelengths longer than 500-1,000 m for radio communication.

THE Think Tank's recent review of energy conservation possibilities (see Nature, July 5) is the subject of five weekly meetings at the Royal Institution where some of the propositions and recommendations put forward in the report will be discussed and criticised. Last week's meeting dealt with the potential of tidal power—on which the report was unenthusiastic—with a quick look at wave power, regarded more favourably by the Think Tank.

The first point stressed by the speakers, Mr David Gwynn and Mr Brian Severn of Engineering and Power Development Consultants—a member of the Balfour Beattie Group—was that tidal power does work and that there is experience available in facing and overcoming the technical problems which arise.

Nobody claims that tidal power is the answer to Britain's energy problem. A scheme in the Severn Estuary, for instance, could provide a maximum of 4.5 GW and would save about 5 million tonnes coal equivalent each year in fossil fuels. But it is an inexhaustible resource and, even on the limited scale that would be possible in Britain, could produce a useful minor diversification of the energy base as part of an integrated power generating system.

#### There is a tide . . . .

The disadvantages of tidal power when viewed simply as an isolated source of electric power generation are to some extent mitigated when it is considered as part of a total energy system. The snags are, of course, that power generation is irregular. In any period of 25 hours there will be four periods of slack water when power cannot be generated and the range of tides also varies considerably.

The possible role of tidal power in providing a source of heat for district heating would be one way of overcoming the disadvantages of irregular power generation. Mr Gwynn and Mr Severn also see a role for tidal power in smaller local projects (not necessarily in Britain) in integrated schemes for estuary basins involving water storage, and in recreation (yachting, for example) with a small tidal power station serving some local use such as pumping water for irrigation.

One of the assumptions in the Think Tank report was that water storage and power generation in the same estuary would be incompatible. This was challenged by Mr Gwynn who pointed out that limited freshwater storage in 'bunded' reservoirs would not interfere with tidal movement. Larger schemes

for barrages across the mouth of the estuaries for water storage are now to some extent out of favour.

Compared with tidal power, the practical capabilities of wave power are as yet untried. And there are still many unsolved problems such as storing the power generated and transmitting it to the shore, quite apart from the possible technical difficulties in manufacturing the massive steel structures which are needed for the most promising scheme involving wave power.

But in the long term wave power could theoretically provide an inexhaustible source of almost all Britain's energy requirements, and is the one new 'unconventional' source of power singled out by the energy conservation report as worthy of serious investment and consideration.

Some wider implications of the use of wave power were touched on by the meeting chairman, Professor John Page of the University of Sheffield. What effects, he wondered, would the presence of strings of these massive structures out in the Atlantic have on overall wave movement and what could be the consequences to coastal ecology and fisheries? Also, in the present confusion and uncertainty over the rights of nation states over the oceans, would there also be objections on legal grounds?

#### **Bacterial** engineering

SIR.—The anxiety expressed by various scientists on the hazards of partially hybridising certain types of microorganisms has already led to considerable public disagreement. It is clear that some responsible and established workers consider it unwise to take humanity with them on any tour into the unknown, while others consider it impractical to curtail the spread of organisms by any method proof against technical errors, psychoses, and even earthquakes. This will remain true whatever is stated by any of the many committees which are likely to advise each advanced nation.

I wish to advance a simple positive proposal which cannot fail to increase the safety of any bacterial incorporation studies, and which would itself provide interesting examples of extreme adaptation which might have applications to other fields, such as waste disposal.

Contracts should be offered for the development of an organism, with suitable qualities for work on partial

hybridity, which would not grow within a pH range of 6–8, would need an oxygen partial pressure of at least three-fold the normal, and which was dependent on at least two unusual synthetic substrates. These should be very simple safeguards against any single mutation allowing reproduction in any natural host.

Once such an organism was established, it should only be necessary to provide substantial subsidies to firms undertaking to provide the necessary culture media—and such media could hardly be misappropriated—to provide an economic and technical climate within which temptations to continue to work on the worst possible organism—a commensal of the human gut—would be seen as both unnecessary and irresponsible.

Since even bacteria take time, and moratoria cannot be expected to contain curiosity for long unless alternative outlets are provided, and seen to be imminent, the matter would seem urgent, and probably too urgent for the attention of the present public funding

organisations. Even if no immediate funds are available from such sources informed discussion might influence some companies which supply media and equipment for tissue culture to initiate work in the hope of reaping the large commercial rewards such developments could yield.

J. H. EDWARDS Queen Elizabeth Medical Centre,

Why then publish?

Birmingham, UK

SIR,—Recently I was a co-author on a paper in *Biochim. biophys. Acta*. Of the 140 reprint requests addressed to me no less than 70.5% were addressed to an unknown Dr B. R. Carter. I hope this frequent oversight is not a reflection on the powers of observation of the modern scientist. Perhaps this is one way of discouraging people from publishing too many papers: deny them the right of recognition.

Yours faithfully,

B. R. CATER

Sheffield, UK

SIR,—It is regrettable that your journal should have given such prominence to an article-"Doubts Over US in India" (Nature, September 20)-consisting of vague allegations and innuendoes against respected scientific bodies. In the entire article I found only three factual statements capable of verification (the others being matters of opinion) and these are quoted from a letter to a newspaper. For the rest, the author seems to rely on unnamed "Indian scientists" or "experts". No names or designations are given and it is difficult to place much value on such anonymous allegations.

I would like to state the facts about the Bombay Natural History Society and its collaborative research with the World Health Organisation (WHO) and other organisations, with which I have been personally connected, so that your readers have an opportunity to form their own judgement of the matter.

In 1957 a 'new' virus disease was detected in Mysore State. This Kyasanur Forest Disease (KFD) virus closely resembled the virus of Russian Spring Summer Encephalitis and raised the possibility that the disease was brought to India from Siberia by arthropod vectors carried by migrating birds. A collaborative study of the problem was organised by the WHO, under Dr Salim Ali as principal investigator, in which the Bombay Natural History Society studied the migratory birds and the Virus Research Centre, Poona, carried out the virological studies on the birds and their parasites. After some time, it seemed that transmission of disease by this route, though possible, was not a significant epidemiological or public health problem. The WHO, accordingly, discontinued its support of the programme. The Bombay Natural History Society continued to work, although no virological studies were possible since neither the Virus Research Centre nor the Haffkine Institute (where I was then Head of the Department of Virology) could spare the necessary staff for a study. For • a time, at the instance of the WHO, blood samples were sent to the Institute of Diseases with Natural Foci at Omsk, since many migrant birds come to India from that area.

At about this time the United States Army Migratory Animal Pathological Survey (MAPS) organisation was studying migratory animals and a proposal for continuing the bird migration study in collaboration with them was accepted with the approval of the Indian Ministry of Defence. No American scientist was designated for this programme by the MAPS. In addition to the migration studies, blood smears from the birds were collected and, at the outset, were sent to the

MAPS for study. Such slides could have been provided to any other agency interested. After a while the MAPS discontinued this study and several hundred slides are still at the society awaiting study by some interested party.

Subsequently grants under PL480 funds were made to the Bombay Natural History Society in collaboration with the Smithsonian Institution for a study of bird migration, and this continued until 1973 when all PL480 grants were stopped by the Indian government. These grants are made for

# Answer from India

from A. N. D. Nanavati, Bombay Natural History Society

collaborative research programmes approved by both the United States and India, and are operated by scientists from both countries. The Indian government does not accept any such research programme without careful scrutiny by independent experts. There are hopes that the grants for this study may be revived.

The main point on which suspicion has been focussed is the collaborative study with the MAPS, because of the fear that information so obtained may be useful in biological warfare. So long as there is no secrecy involved, there can be no objection to any research, otherwise we would be constrained to ban every textbook on epidemiology and communicable diseases. This research programme was open and the information was available to anybody interested. The bird camps were visited by ornithologists and other scientists from several countries (including workers from the Institute of Diseases with Natural Foci, Omsk) all of whom had full and free discussions on the information collected. Much has also been made of the proviso that the MAPS

required that no material be published without clearance from it. There was no such provision in our contract, merely that the MAPS should receive two advance copies of any publication or report. With this information, the only factual charges made by 'a professor' and quoted by Mr Sehgal can easily be disposed of:—

- (1) That blood smears were sent to the MAPS for examination. They could also have been and can still be made available to any other interested party.
- (2) That two US scientists from the Smithsonian Institution were associated with the Bombay Natural History Society. One scientist, Dr Dillon Ripley was designated as the American Investigator and Dr Salim Ali was the Chief Investigator from India. This was part of the routine in any PL480 financed study.
- (3) The services of the Bombay Natural History Society and the Virus Research Centre were made available to United States Army personnel for a nominal fee. This seems to be a figment of someone's imagination. Neither the Bombay Natural History Society nor the Virus Research Centre are commercial organisations. The Bombay Natural History Society offers assistance to any serious student, wherever he comes from. No charge is made for such assistance.
- (4) That only partial results were available to the Indian participants. We have, in India, people of sufficient experience in epidemiology and microbiology to be able to assess the significance of these studies and to detect whether there were any significant omissions or false information in the results supplied. This charge is, however, a matter of opinion which could only be resolved if Mr Sehgal would disclose some of the information which he claims has been withheld.

It seems then that the gravamen of Mr Sehgal's charges is that all the Indian scientists working on collaborative research programmes with international or foreign agencies are gullible and will believe whatever their collaborators tell them. He therefore ignores the considered statement made by our President, Dr Salim Ali, but would place his faith in the rumours and 'feelings' of anonymous authorities, unsupported by a single verifiable factual statement. Can it be that there is no monopoly on gullibility?

This is not to suggest that we can afford to be careless. Dangers do exist and must be carefully guarded against. It is unfortunate that in trying to highlight possible dangers Mr Sehgal has cast aspersions on institutions and persons who are fully aware of their responsibility and have taken all possible safeguards against such dangers.

# news and views

### No consensus yet on climate

In this issue of *Nature* (pages 368 and 370) is another instalment of the saga in which non-meteorologists suggest to the professionals processes, hitherto unrepresented, that may account for their lack of forecasting skill. The meteorologists' usual response is, as Sawyer's here, that it is not dubious new processes that are required but better understanding of those already known to be important.

Meteorologists are acutely aware that their data are so abundant that fortuitous associations of some of them with unrelated phenomena are bound to exist. To some extent King's scholarly conjectures about the association of magnetic field and climate are liable to this reservation. Sawyer shows, moreover, that there has been some selection of data in King's quoted evidence—the association he describes is much better for latitude 60° N in the winter than for other latitudes and seasons.

But I was still a little surprised at Sawyer's comment which is based on the fidelity of current numerical models of the atmosphere and in particular with his degree of confidence in what is, after all, one of the less sophisticated models of global-scale processes. To my mind this is deftly and succinctly qualified by King's reply, and one should indeed bear in mind a further qualification. The numerical models of atmospheric circulation do not represent quite such pure physics as might be supposed at first sight, for they have to be 'tuned'. By this process values of parameters appearing in the models are adjusted to make the model behave more realistically such processes as surface friction, the transfer of energy by electromagnetic radiation and many cloud effects usually have to be treated in this way. Although this is a legitimate way of establishing a mutually consistent set of interacting processes, there is clearly room for King's as yet unidentified process.

The evidence for an association of geomagnetic and meteorological patterns presented by King is tempting (cor-

relations of 0.96 are not to be sneezed at). Causal connection is a remote possibility awaiting a plausible quantifiable hypothesis that is not even remotely hinted at by King. His speculation that "Coriolis force, inertia and viscosity of the air" may account for some differences seems naive. Meteorologists know about such things and have taken them into account in many elegant and detailed treatments which show how the atmosphere responds to any forcing, whether by anomalous heat sources, undulation of surface elevation or indeed ill-defined but energetically small magnetic effects. Such analysis shows that motion of large scale penetrates upwards high into the atmosphere, where the energy is partially reflected downwards. Such reflection is governed by the large-scale properties of the upper layerslike the general wind and temperature structure, which may indeed be conditioned by some much less intense energy sources.

Given finally that the large scale systems may be close to resonance (particularly in the winter) we have the beginnings of some process by which climate may be modified by weak energy sources, especially those in the upper atmosphere but, it must be stressed, dependent not on local anomalies of energy but on variability of the global scale circulation.

If causal effects of one on the other are unlikely, is it possible that both climate and magnetic field perturbations have a common origin? It is widely believed that the details of the geomagnetic field originate at the core-mantle boundary, if not in the core itself—an unlikely spot, one would think, for climate to be controlled from. But the obvious influence of continents on climate and the less obvious influence of continents on upper-mantle resistivity profiles could, just conceivably, be a link—the upper mantle being a window through which core effects are seen.

J. S. A. GREEN

### The self control of myosin

Two recent papers have reopened the debate about the existence of a Ca<sup>2+</sup>-sensitising mechanism associated with the thick filaments in vertebrate muscle.

By the late 1960s it was generally believed that contraction of vertebrate skeletal muscle—and by assumption also of other muscles—was triggered solely by the binding of Ca<sup>2+</sup> ions to the troponin components of the thin filaments. The evidence for this was that troponin was apparently the only myofibrillar protein which could reversibly bind Ca<sup>2+</sup> in the presence of Mg<sup>2+</sup> ions and that troponin, together with tropomyosin, was required to confer Ca<sup>2+</sup> sensitivity on the ATPase of vertebrate skeletal actomyosin.

The idea that all muscles were controlled through the thin filaments in this way was scotched by a series of papers by Szent-Györgyi, Kendrick-Jones and Lehman. They were able to show that whereas some invertebrate muscles had this troponin control, others (most notably certain molluscan muscles like the cross-striated adductor muscle of *Pecten*) lacked troponin but instead contained a special

kind of myosin which could bind Ca<sup>2+</sup> in the presence of Mg<sup>2+</sup> ions. Correspondingly, the actin-stimulated myosin ATPase from such muscles was Ca<sup>2+</sup> sensitive. In other words, such muscles were controlled through the myosin of their thick filaments. Yet other invertebrate muscles had both forms of control. The test devised to determine which kind of control is present in any given muscle is simple. The effect of adding pure actin to the contractile apparatus is observed. If the Ca<sup>2+</sup> sensitivity (that is the ratio of the ATPase activity in the presence and absence of Ca<sup>2+</sup> ions) is reduced, then only the troponin control must be present since the thin filament activity has been swamped by the excess unregulated actin. But if the sensitivity is unaffected there must be myosin control.

Szent-Györgyi et al. examined both smooth and striated muscles of invertebrates but only the striated muscles of vertebrates. Now Bremel (this issue of Nature, page 405) has applied their test to a vertebrate smooth muscle (chicken gizzard), about whose control little is known. The

addition of pure actin has no effect on the Ca<sup>2+</sup> sensitivity of a crude preparation of chicken gizzard actomyosin. This shows that a myosin control is present. To see whether or not troponin control is also present, Bremel has applied the complementary test. The addition of rabbit heavy meromyosin to the preparation reduced the Ca<sup>2+</sup> sensitivity. When due allowance is made for the activity of the chicken gizzard myosin, it turns out that the added heavy meromyosin ATPase (stimulated of course, by the chicken gizzard actin) is not Ca<sup>2+</sup> sensitive. Bremel concludes that vertebrate smooth muscle lacks troponin and is analogous to those invertebrate muscles which have only myosin-linked calcium regulation.

Even in vertebrate skeletal muscle there is growing evidence for a thick filament control. A few years ago, Haselgrove and H. E. Huxley examined by X-ray diffraction muscles stretched to lengths where no overlap would be expected between thick and thin filaments. Nevertheless on stimulation of the muscle, movements of the myosin heads, recognised by a loss of their helical order, could be observed. The simplest interpretation was that the thick filaments of vertebrate skeletal muscle were themselves directly responsive to Ca<sup>2+</sup> ions. Possibly, however, some overlap of filaments was still present in local regions of the fibre and changes in the region of overlap were propagated to the rest of the thick filaments. Because there was this doubt, the significance of these important experiments was not immediately felt.

A change of thick filament conformation should affect its sedimentation coefficient. So Morimoto and Harrington (J. molec. Biol., 88, 693; 1974) have examined the rate of sedimentation of isolated natural thick filaments in the presence and absence of Ca<sup>2+</sup>. A small but significant increase in the sedimentation coefficient with rise of Ca<sup>2+</sup> concentration is indeed observed. The midpoint of the transition is at a Ca<sup>2+</sup> concentration of about 3×10<sup>-6</sup> M (well below the level of Ca<sup>2+</sup> thought to be reached inside an activated muscle fibre) and is rather insensitive to the Mg<sup>2+</sup> concentration. Hydrodynamic theory is unfortunately too complicated to say exactly what changes in conformation are responsible for the variation in sedimentation coefficient.

Similar experiments with synthetic thick filaments prepared from purified myosin establish that myosin, rather than C-protein, is the  $Ca^{2+}$ -sensitive protein. This was surprising since it has been assumed that vertebrate skeletal myosin binds little  $Ca^{2+}$  in the presence of concentrations of competing  $Mg^{2+}$  ions similar to that in muscle ( $\approx 1 \text{ mM}$ ).

Morimoto and Harrington have gone on to redetermine the Ca<sup>2+</sup> binding properties of myosin in the presence of Mg<sup>2+</sup>. They find that each myosin molecule has two Ca<sup>2+</sup> binding sites with an affinity accounting for the sedimentation data. The sites turn out to be located on the light chains removable by 5,5' dithiobis-dinitrobenzoic acid (DTNB). It remains to be seen how the binding of Ca2+ ions to these chains could produce large-scale movements of the myosin heads. It is just possible that the DNTB light chains are not associated with the heads themselves (as is generally thought) but rather with the 'necks' joining the heads to the tail of the molecule. In this position they could perhaps influence the movements of the heads. The point of special interest is that the DTNB light chains of vertebrate skeletal myosin were recently shown to be capable of substituting for the Ca2+-sensitising light chains of Pecten myosin (see Nature, 249, 609; 1974) which suggests a considerable similarity between the two kinds of myosin. Nevertheless, the temptation to think of the myosin control in vertebrate skeletal muscle as being entirely analogous to that in invertebrate muscle should be resisted for the moment. There remains an important difference to explain: the actomyosin ATPase of vertebrate skeletal muscle is not sensitive to Ca2+ ions, whereas that of Pecten actomyosin is. In other words evidence is lacking that the regulation of cross-bridge movement by Ca<sup>2+</sup> affecs ATP consumption. Whether this difference is attributible to a greater lack of spatial organisation of the verterate filaments in experiments conducted in the test tube remains to be seen. We can certainly expect a spate of papers probing this problem.

The conclusion that in vertebrate skeltal muscle there is control through the thick filaments as well as the thin filaments is attractive. It always seemed priverse of nature to control cross-bridge activity through the thin filaments when a more obvious form of control would be to regulate the movement of cross-bridges directly. The existence of two Ca<sup>2+</sup> sensitising mechanisms, one on each kind of filament in vertebrate skeletal muscle, would presumably increase the sensitivity of the contractile apparatus to Ca<sup>2+</sup> ion concentration and ensure that the breatdown of ATP in resting muscle was kept at a low leve. The relative importance of the two forms of control remains to be assessed.

# More false hopes about solar neutrinos

One of the principle activities of stellar astrophysicists in the last five or six years has been to tackle the solar neutrino puzzle. Since Davis and his collaborators announced an upper bound to the flux of neutrinos incident on the earth from all sources which was only one tenth the value theorists had predicted from the Sun alone, astrophysicists have rightly been concerned about their understanding of the Sun. Initially there was a massive reappraisal of the theory, and in particular of the nuclear physics needed for computing the rates of the energy and neutrino producing reactions in the solar core. Improvements were made both to the equations governing the solar models and to the numerical methods used to solve them. But on the whole these did not change the theoretical solar neutrino flux by nearly as much as was necessary.

Perhaps the most profitable activity was to adjust certain inaccurately known parameters, such as those defining the initial conditions. This led to the construction of what has become known as the 'standard model': namely, that solar model with all such parameters adjusted to the limits of plausibility in such a direction as to minimise the predicted neutrino flux. There are now several standard models, independently computed by different workers, and all yield similar neutrino fluxes rather lower than the pre-Davis values. As to the state of the measurements, Davis has refined his techniques and now quotes an upper bound which, in round numbers, is still about a factor ten below the theoretical values.

The recognition that standard models would probably never fit the observations has provoked much questioning of the premises from which they have been constructed. Most of the papers published are of an exploratory nature, asking merely the question: "How can the theoretical neutrino flux be reduced below Davis's limit simply by arbitrarily though not entirely implausibly adjusting the unconfirmed assumptions of the theory?" A complete answer to that question would be a very valuable first step towards the solution of the puzzle.

One line of investigation has been to postulate that the inside of the Sun is rotating much faster than the surface. Early calculations along these lines were unsuccessful, but recently Demarque, Mengel and Sweigart (Astrophys. J., 183, 997; 1973; Nature phys. Sci., 246, 33; 1973) and Roxburgh (Nature, 248, 209; 1974) have produced models which they thought predicted neutrino fluxes below the observed

flux bound. These models have extremely rapidly rotating cores with the ratio  $\lambda$  of centrifugal to gravitational forces being as high as  $\frac{1}{4}$  to  $\frac{1}{2}$ .

But a serious flaw in the calculations has recently been pointed out by Monaghan (Mon. Not. R. astr. Soc., **169**, 13P; 1974) The rapidly rotating models were computed under the assumption that \( \lambda \) is very small, and approximations essentially equivalent to using  $1 + n\alpha\lambda$  for  $(1 + \alpha\lambda)^n$ , where  $\alpha$ is of order unity, were used. In the calculations of the neutrino flux n is typically between 25 and 30, and for such values, Monaghan points out, the approximation leads to gross underestimates when  $\lambda$  is as large as Demarque et al. and Roxburgh require, whatever the sign of  $\alpha$ . It seems, therefore, that even allowing for the errors arising from this approximation in the calculation of the mean energy generation rates, the quoted theoretical neutrino fluxes have been underestimated by at least a factor three.

A second criticism is raised in today's issue of *Nature*. Rood and Ulrich (page 366) have repeated the calculations

of Demarque et al. and have argued that the latter authors made a mistake in their computation of the oblateness of their models. This is admitted by Demarque et al. on page 368. When the mistake is put right, the oblateness comes out to be greater than the measured value that R. H. Dicke reports. Roxburgh's model is not ruled out by Dicke's measurements, but it is contradicted by the recently announced results of the more careful investigations by H. A. Hill and his collaborators, which imply an almost spherical Sun consistent only with a rotation of the interior hardly faster than that at the surface.

Rood and Ulrich go on to investigate the combined effect of rapid rotation and a postulated transient convective mixing triggered by shear turbulence. Of course this raises the obvious difficulty of justifying why the Sun is in a unique peculiar transient state at the present time; but in any case the models presented today fail to yield sufficiently low neutrino fluxes combined with an adequately small oblateness, even though they are based on

the small  $\lambda$  approximation and are subject to Monaghan's criticism. Rood and Ulrich conclude that rapid rotation is not a clue to the solution of the neutrino puzzle. They are probably right.

D. O. Govon

# Inbreeding to preserve diversity

from our Animal Ecology Correspondent In the Uganda kob antelope there exists a system of social behaviour clandestine to prevent designed matings. Individual males fight for and guard small territories of between 10 and 20 m in diameter. A cluster of 30 to 40 such territories is called a lek. In the Torro Game Reserve in Western Uganda there are 18 such leks in an area of 400 km2. Courtship and mating take place within the territories amid a complex ritualised dressage which seems to be designed as if to publicise the fact that a mating has taken place. The details of the lek behaviour are well known (Buechner, Science, 133, 698; 1961; Proc 16th int. Congr. Zool, 3, 59; 1963), but what is not well known is why clandestine matings should be frowned upon.

Buechner and Roth (Am. Zool., 14, 145; 1974) have investigated the possibility that the total population is divided into socially defined breeding demes, each of which occupies a lek. Most leks persist for long periods in the same place-of the 15 major leks serving the Torro Reserve now, 10 are in traditional locations which can be dated back at least to 1959. Evidence that animals breed only within a lek comes from tagging data and from translocation experiments. Most territorial males are found within 500 m of their home lek 90 to 100% of the time. Females are less attached to the site but all known individuals returned to the home lek for breeding. Until they reach 11 years when they settle down in a lek, fawns seem to have little attachment to any particular site but on no occasion did an adult male translocated to a foreign lek succeed in establishing itself.

Morphological data, such as ear, tail and hind leg length, provide further evidence of inbreeding. There was significant variation between leks in males' hind leg and ear length, and females' body and tail length. Yet more evidence came from the animals' altruistic behaviour which, according to Hamilton (Man and Beast: Comparative Social Behaviour, edit. by J. F. Eisenberg and W. S. Dillon, 59 Smithsonian Institute Press, Washington; 1971) is directly related to the degree of kinship within a population.

### Raindrops in the laboratory

from our Chemical Physics Correspondent

Drops of water, and eventually rain, grow from small droplets as they fall under gravity through slightly supersaturated air. Such a system is difficult to study in the laboratory as the droplets whose growth is of interest do not remain long in the field of view of any microscope and, unlike snowflakes, the drops can not reasonably be collected and studied at leisure.

Gollub, Chabay and Flygare (J. chem. Phys., 61, 2139; 1974) have applied the special properties of the argon ion laser to this problem with great success. Basically the droplets scatter the laser light and, because of their falling motion, they impart a Dopper shift to the light frequency of the order of 500 Hz. The exact shift will depend on the velocity of fall of the droplet through the viscous air and hence on the size of the droplet which can therefore be deduced from the Doppler shift. The shift can be accurately measured by beating the scattered light with light, unshifted in frequency, scattered from the stationary walls. The effective scattering volume is only 0.02 cm3 and is well defined in location so that the droplet size can be measured as a function of position in the sample chamber. This is 3.5 cm high internally and 10 cm in diameter so that control of temperature, of air purity and of supersaturation are straightforward to apply. Clearly different conditions are possible but in the experiments reported at 7° C and a degree of supersaturation of the order of 4%, the mean droplet radius is about 3  $\mu$ m towards the top of the chamber and increases to about 7  $\mu$ m as the particle falls to the bottom. At any specific point the distribution of drop sizes about the mean for that point is remarkably narrow, for example,  $\pm$  0.2  $\mu$ m in 4  $\mu$ m about 2 cm below the point at which nucleation occurs.

Confirmatory evidence on the particle size measurement is obtained from the scattering intensity. The growth of the droplets as a function of the distance they have fallen provides information about the growth mechanism; the results support a reasonably high thermal accommodation coefficient and even the value unity is not excluded. The condensation coefficient seems to be less than unity but doubtless further work will improve the details of the theory of drop growth. Though the results from these first experiments are important, probably even more important is the introduction of a new, informative and fairly simple and inexpensive technique which will enable the formation of water droplets and of rain to be extensively studied in the future.

The kob antelopes show altruistic behaviour in that individual males do not pursue females into neighbours' territories, victors of border disputes do not inflict serious wounds on losers, and individuals expose themselves in a conspicuous manner to predators inviting attack from a 'safe' distance. The latter behaviour has been investigated in detail by Smythe (Am. Nat., 104, 491; 1974).

Thus the courtship customs and social behaviour of each lek seem effectively to prevent matings outside the lek. Such matings are rare and their illegitimate offspring rarely survive. Social behaviour therefore maintains the genetic heterogeneity of the population by preserving the differences between leks. This ensures that there is sufficient genetic scope for evolution if conditions change, a mechanism which is probably especially important for the preservation of alleles with a small selective advantage (Wright in The Evolution of Life, edit. by S. Tax, 429, University of Chicago Press; 1960). A solution also exists in this successful species population to the problem of maintaining a certain amount of gene flow-every so often temporary leks are formed, lasting one to five years, after which time animals return to their original lek.

### Phonon transmission

from P. V. E. McClintock

THE transmission coefficient of phonons travelling from a silicon crystal into superfluid helium exhibits a maximum when the phonon energy corresponds to a temperature of about 5 K, according to a thermal pulse experiment by Swanenburg and Wolter of the Philips Research Laboratories at Eindhoven described in a recent issue of *Physical Review Letters* (33, 882; 1974).

The thermal energy in a crystal at low temperatures takes the form of quantised lattice vibrations known as phonons, which behave much like a gas of free particles each travelling at the velocity of sound. At any given temperature T the average energy of the phonons present is  $\sim kT$  where k is Boltzmann's constant, so that an increase of T not only causes an increase in the phonon density, but also brings about an increase of their average energy.

It has long been known that, when heat passes from one material to another, there is a discontinuity in temperature at the junction. The phenomenon can be understood in terms of an acoustic mismatch theory: just as in the case of light which undergoes partial reflection when incident on the interface between two media in which its velocity is different, so also are

phonons partially reflected if the velocity of sound differs in the two materials, thus affecting the transmission of thermal energy between them.

The velocity of sound in liquid helium is about an order of magnitude smaller than in most solids, so that there is a correspondingly large temperature discontinuity when heat passes between liquid helium and a solid, describable in terms of a thermal boundary resistance called Kapitza, the Russian physicist who discovered the effect. For  $T \le 1$  K values of the Kapitza resistance measured in equilibrium heat flow experiments are in reasonable agreement with those predicted by an acoustic mismatch model. When  $1 < \mathbb{Z} < 2$  K, however, the Kapitza resistance falls below the predicted values by an order of magnitude or more, an effect which is still not understood and which Swanenburg and Wolter have sought to investigate by means of their heat pulse technique.

Their experimental arrangement consisted of a very high quality silicon crystal, one face of which was in contact with liquid helium and the opposite face of which was in vacuum. A thin resistive metal film heater was deposited on the latter face. By applying an electrical pulse to the heater, high energy phonons could be generated, all of which necessarily passed into the silicon. A certain proportion of the phonons incident on the siliconhelium interface travelled on into the helium where they generated a pulse of the thermal wave mode known as second sound, which could be detected by a bolometer positioned a few millimetres away. The size of the bolometer signal was proportional to the energy flux entering the liquid. Because of the thermal discontinuity between them it was possible to heat the metal film to a very much higher temperature than that of the crystal. Thus it was possible to transmit phonons of energies equivalent to as much as 34 K into the crystal at 1.8 K, and then to investigate what proportion of these high energy phonons was transmitted into the liquid helium, which also remained at 1.8 K.

Unexpectedly, the authors found that although the transmission coefficient increased as the average phonon energy rose from 2 to 5 K, it then passed through a maximum and subsequently decreased as the energy was raised further. They describe a number of detailed checks, involving the use of heaters with different surface areas, which they have carried out in order to ensure that the change in the bolometer signal was really due to changes in the phonon transmission coefficient at the interface, and was not an artefact arising from some frequency dependent process in the crystal: they conclude that the phenomenon is genuine.

A new theory of he Kapitza resistance is therefore required which can not only explain why the transmission of thermal energy across a solid-liquid helium interface is anomalously enhanced above 1 K, but which is also able to account for 3 wanenburg and Wolter's conclusion that the responsible mechanism decreases in efficiency as T is raised above 5 K.

# High speed colour schlieren photography

from J. Kim Vandiver

THE cover picture of the bullet and candle is a colour schliesen photograph. It exploits techniques that were first used by August Toepler in 1864, and later by Schardin, who developed the first colour system in 1934. Though many improvements were made, until 1971 all colour methods gave only onedimensional information about the density gradients in the test section. In 1971 a technique was described (Strong and Settles, Scient. Am., 225; May 1971) which simplified the equipment and made possible colour photographs with fully two-dimensional density gradient information. These optical refinements were combined with a submicrosecond light source and triggering device to photograph a variety of transient events.

Refraction occurs when light encounters a region of non-uniform index of refraction. The refraction will be toward the region of increasing index in proportion to the gradient of the index perpendicular to the direction of travel. Natural events that cause changes in the pressure, density or temperature in the media around them ultimately alter the refractive index. Schlieren techniques discriminate light that has been refracted by a physical event from the remainder of the light in the test section. Once isolated, this light is focused by the camera into an image of the original disturbance.

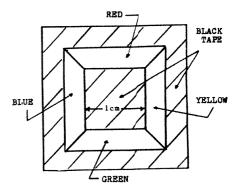

Fig. 1 Source filter

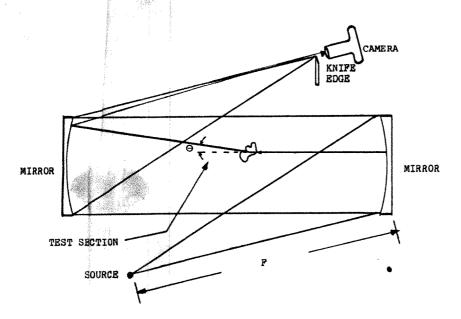

Fig. 2 Mirror system

Figure 2 depicts a simple schlieren system, consisting of two parabolic mirrors with a small light source at one focus and a knife edge and camera at the other. The test section is located in the collimated beam. The knife edge blocks the undisturbed image of the source, but lets pass light which has been refracted and deflected away from the knife edge. This yields a one-dimensional black and white photograph of the gradients in the test section.

The technique used here requires a multicoloured filter at the source, constructed as shown in Fig. 1, and four knife edges arranged to form a square aperture. The colour photograph so obtained indicates the direction of the gradient of the index of refraction by the hue of the colour in the photograph. The complete colour spectrum is used to provide 360 degrees of directional information.

Schlieren systems are very inefficient users of light. Most of the light available in the test section is rejected at the knife edges. To achieve properly exposed colour photographs requires intense light sources or long exposure times. To capture a supersonic bullet, or the shock waves from an electric spark, requires exposures of less than a microsecond. Our photographs employed an E. G. & G. Microflash Unit. This device discharges a 0.05 mF capacitor at 17 KV through a 2.5 cm air gap. Seven watt-seconds are discharged in  $3 \times 10^{-7}$  seconds. The light produced is focused by a reflector on to the rear of the coloured filter. Initial tests indicated that a small camera format and a fast colour film were required. A 35 mm format and High Speed Ektachrome (ASA 160) film were selected. A 400 mm telephoto lens was required to match with the 0.273 m

diameter, 2.46 m focal length parabolic mirrors, to yield an image size appropriate to the 35 mm format.

A variety of supersonic bullet photographs were taken. Bullet shock wave interaction with candle flames, soap bubbles, and solid objects was photographed revealing reflected, refracted and transmitted shock phenomena with excellent clarity. Bullet photographs were triggered, using a microphone, by the passage of the shock wave. Open air gap sparks, generating spherical shock waves, were photographed in air and water. Triggering was accomplished by a photocell and a variable time delay. Vortices are shed by propellor tips of an ordinary fan. These can be photographed when hot air from a flame is entrained by the vortex. Real time viewing with a synchronous strobe behind the filter is most revealing. More photographs may be found in Strong and Vandiver, Scient. Am., 231; 105; 1974.

The simplicity and versatility of this schlieren system are assets which make colour schlieren photography an attractive tool for scientific investigation, apart from its extensive use in supersonic wind tunnels. Other features include high resolution and sensitivity and pleasing colour results.

# Diseases of fodder crops

from A. I. H. Carr

FORAGE and fodder crops occupy about 75% of the agricultural area of the United Kingdom and contribute two thirds of the livestock intake. Perhaps surprisingly, the limitations imposed by disease on optimum output from these crops are only now becoming gener-

ally recognised. This was the opening theme of a symposium, "Diseases of forage and fodder crops" held at the British Museum (Natural History) on November 1 under the auspices of the Federation of British Plant Pathologists.

Introducing the topic, Dr A. J. H. Carr (Welsh Plant Breeding Station, Aberystwyth) referred to the difficulties of assessing yield losses in herbage crops which consisted of mixtures of outbreeding species grown together in competition, managed and utilised in many different ways, and with an ultimate yield assessed as animal production. Despite these difficulties, experience has revealed that infection with pathogenic fungi and viruses could cause adverse changes in botanical composition, loss in (and altered seasonal patterns of) productivity, and reduced nutritive value.

Dr A. J. Heard (Grassland Research Institute, Hurley) and E. T. Roberts (Agricultural Development Advisory Service, Reading) said that two thirds of grass crops surveyed had suffered damage due to disease and management problems in roughly equal proportions. They and others, referred to the damage to ryegrass, the predominant sown grass species, caused by crown rust, drechslera leaf spots and foot rots, and viruses such as ryegrass mosaic and barley yellow dwarf. Crown rust disease could reduce ryegrass productivity by 20% when compared with resistant varieties or plots protected by systemic fungicides and it also affected regrowth (Dr C. O'Rourke, Oak Park Research Centre, Carlow, Eire). The carbohydrate content of grasses could be reduced by half following infection with fungal leaf pathogens, and ryegrass mosaic virus reduced yield by 30% and accentuated winterkill. A valuable contribution came from F. G. Cook (Huddersfield Polytechnic) who described methods of relating production loss under various management systems to lesion development in ryegrass infected with Drechslera spp., which would have application to the study of other grass leaf pathogens. Dr E. G. Gray\*and J. F. Copeman (North of Scotland College of Agriculture) discussed the special problems arising where winter damage following extended snow cover is intensified by snow moulds (Fusarium nivale and Typhula incarnata). This influences the choice of ryegrass varieties towards those less susceptible to these pathogens. A different type of winterkill not associated with snow cover but dependent upon cold weather was described by Dr J. I. Holmes and Dr A. G. Channon (West of Scotland College of Agriculture). They showed experimentally that damage by Fusarium nivale was considerably increased if the inoculated grass was exposed intermittently to low temperatures.

Dr G. R. Dixon (National Institute of Agricultural Botany, Cambridge) drew attention to the increasing prolem of clover rot in white clover and discussed keys for assessing varietal resistance which existed in both red and white clovers.

The epidemiology of virus diseases, which are systemic and often transmitted both by contact and animal vectors, was the subject of papers by Drs R. W. Gibson and R. T. Plumb (Rothamsted Experimental Station, Harpenden) and by J. A'Brook (Welsh Plant Breeding Station, Aberystwyth). The Rothamsted workers, by using a filtered-air ventilated polythene tent over the crop to exclude mite vectors. were able to show that mechanical transmission played only a minor part in the spread of ryegrass mosaic virus. By contrast, the Aberystwyth work indicated that mechanical transmission was the predominant feature in the spread of the beetle-transmitted cocksfoot mottle virus. Large catches in the autumn in west Wales of aphids carrying barley yellow dwarf virus to grass and cereal crops were associated with low wind speeds, low precipitation and a prevailing southerly wind. Dr Plumb also drew attention to a number of virus problems in continental Europe which were potentially dangerous for the United Kingdom.

As the opening speaker had remarked, the solution to the problem of crop losses lay in applying the knowledge gained to the development of sound management techniques and the production of resistant varieties. Progress in resistance breeding was reported by P. W. Wilkins for crown rust and ryegrass mosaic virus and by T. D. Johnston for mildew and clubroot in swedes and rape (Welsh Plant Breeding Station, Aberystwyth). In view of past experience with pathogens of other crops it was gratifying to note that plant breeders were aware of the dangers of using simply inherited resistance, particularly to air borne pathogens, although for clubroot, caused by a soil-borne pathogen with a slower dissemination of genetic variants, such resistance could be beneficial.

Due emphasis was also laid on the nature of resistance. Mrs J. A. Chamberlain (Welsh Plant Breeding Station, Aberystwyth) presented evidence to show that tolerance in breeders' material to ryegrass mosaic virus was associated with certain ultrastructural features such as the size and number of pinwheel inclusions in host cells. Similar phenomena were associated with the tolerance of wheat to agropyron mosaic virus. J. A. Hargreaves and Dr J. W. Mansfield (University of Stirling) demonstrated the importance

of the individual components of the multiple phytoalexin response in controlling infection of broad beans by species of *Botrytis*.

Probably the most valuable lessons learnt at this symposium were the gains to be made in production from attention to management and disease problems, and the pitfalls involved in dealing with these complex biological systems.

# Herpesviruses and oncogenesis

from George Klein

The second meeting on this topic, held in Nürnbærg between October 14 and 16, dealt mainly with four types of virus known or suspected to be oncogenic in man or animals: Epstein-Barr virus (EBV) in man, Marek's disease herpesvirus (MDV) in chickens, herpesvirus saimiri and ateles in monkeys, and herpes simplex virus (HSV), defective mutants of which are thought to interact oncogenically with various animal or human target cells.

A central issue concerning EBV is the relationship of findings with animal experiments using virus-carrying cell lines in vitro to clinical findings in man. EBV is now widely accepted as the cause of infectious mononucleosis. Similarly, it may endow the lymphocytes with the capacity for continuous proliferation. Cells from such cultures, which carry multiple copies of the viral genome but only occasionally infectious virus, can produce grow malignantly in immunologically crippled animals such as nude mice.

#### Actiological alternatives

Some workers, including W. and G. (Children's Hospital, Phila-Henle delphia), Dr G. Miller (Yale University Schol of Medicine) and G. Klein (Karolinska Institute), believe that analogous virus-converted cell lines arise in mononucleosis patients or healthy seropositive individuals, but are held dormant, presumably by immunological means. Against this interpretation, however, A. B. Rickinson (University of Bristol) and his colleagues presented evidence from mixing the blood of acute mononucleosis patients with cord blood lymphocytes of the opposite sex. The emerging cell lines contain the sex chromosome of the added cord blood cells as frequently as that of the patient. Since continuous cell lines do not grow from uninfected cord blood cells, they infer that the cord blood cells were transformed by infectious virus released from some cell in the blood of the infected donor. Rickinson and his colleagues propose that EBV can remain latent in vivo in

a state like that of herpes simplex virus in the ganglia. The question remained unsettled, however, in the absence of data from mixture experiments that could have illumnated the derivation of lines from nomal seropositive donors.

In Burkitt's lymphona, EBV-genome tests on biopsy material by nucleic acid hybridisation or by EBNA (EBV-determined nuclear artigen) have led to an unexpectedly starp distinction between the endemic disease in Africa and the sporadic cases that occur elsewhere. Whereas 97% of the African lymphomas were found to carry the genome, the relatively snall number of tumours so far tested from elsewhere were uniformly genome legative. Other lymphoproliferative maignancies also proved genome negative irrespective of the serum antibody titre against EBV.

On the other hand, it has now been shown that cells from EBV-negative lymphomas in seropositive individuals can be superinfected with EBV in vitro. That suggests that those tumour cells which do carry the genome do so because they are derived from a genome-carrying clone, and not as a result of having picked up the virus in vivo. If this is accepted, the two main aetiological alternatives can be referred to as the 'immunological' and the 'cofactor' hypotheses. According to the first, the African BL patient differs from the normal EBV-positive individual only by some deficiency of his immune surveillance. (It must be remembered that BL is a relatively rare disease, even in the high endemic regions.) According to the cofactor hypothesis, EBV-carrying cells would not yet be fully malignant in normal individuals, and some other event would be required for full malignisation. Though at present it is impossible to distinguish between these alternatives, comparison of EBV-carrying lines derived from Burkitt lymphomas, if representative for the malignant clone, and EBV-carrying lymphoblastoid cell lines derived from normal individuals are pertinent to the question. J. E. Jarvis (University of Bristol) reported the presence of a chromosome 14 associated anomaly in 8 of 10 BL derived lines, apparently identical with the marker originally described by Manolov and Manolova. The marker was not found in other EBV-carrying lines. Together with the studies of Nilsson and Pontén that suggested a difference between the morphological, growth and marker characteristics of BL and non-BL derived lines, this evidence was at least consistent with the possibility that the BL lines may represent a special type of cell.

A remarkable change has occurred with regard to the second EBV-genome

carrying humai malignancy, nasopharyngeal carinoma (NPC). This tumour is notorous for its dense lymphocytic infiltration. Since only B lymphocytes were found to carry the viral genome in previous studies in vitro, it has been widely assumed that it is the lymphocytes that carry EBV in NPC. H. Zur Hausen's (University of Erlangen) in situ hybridisation data suggest, however, that the genome is associated with the epithelial cells. Nucleic acid hybridisation data on separated epithelial and lymphoid cells corroborated this conclusion. Klein, Giovanella and Lindahl showed, furthermore, that biopsy derived, nude mouse passaged NPC lines los the human lymphocytes but maintained the viral genome. The EBNA antigen was also present, clearly localised in the large carcinoma cells. These surprising findings will obviously reopen the whole question of the part played by EBV in the actiology of NPC. All available studies concur in suggesting that the genome is associated with the anaplastic or poorly differentiated NPC, but not with well differentiated squamous cell carcinomas at the same or other sites. This raises important questions about the susceptibility of the normal epithelial progenitor to EBV infection and about the part played by the virus in the genesis of the tumour.

In Burkitt's lymphoma, the striking time-space clustering of the disease in the high endemic areas gives clear evidence for environmental factors. In NPC, genetic factors may be more important. It is the most common tumour in certain ethnic groups of Chinese men but is very infrequent in Western populations. In Macao and in Thailand, intermediate incidences were reported for the offspring from intermarriages between the Chinese and non-Chinese populations. In Nürnberg, Simmons presented some new evidence suggesting that NPC patients differ from controls with regard to their HL-A constitution, in line with a postulated genetic risk.

#### Transformation in vitro

In the area of EBV-induced transformation in vitro, there is now firm evidence that different virus strains can differ in their biological characteristics. Y. Hinuma (Kumamoto University) reported differences in the growth, morphological and marker characteristics between lines transformed by the B95-8 and WIL strains. It was not clear whether the differences were determined by the resident viral genomes or reflected a slight difference in the affinity of the two virus strains for different types of lymphoid target cells. Independent comparisons by Menezes (University of Montreal), by Miller

(Yale University) and by Klein et al. showed differences between the P3HR-1 and the B95-8 virus strains. The strains both induce EBNA in comparable numbers of cells, but the unique P3HR-1 virus is unable to transform cord blood or BJAB cells, instead inducing an abortive viral cycle leading to the appearance of early antigen and to irreversible cell damage. In contrast, B95-8 virus has a regularly high transforming activity but fails to induce early antigen. This might suggest that the P3HR-1 line releases a non-transforming mutant virus, but E. Kieff (University of Chicago) reported that it has about 15% more DNA than B95-8 virus.

This has led to an interesting discussion between the herpes simplex workers, E. Kieff and B. Roizman (University of Chicago) in particular, and the EBV workers. Which is the wild type virus and which is defective? Looking at it from the lytic herpesvirus field, the transforming virus tends to be regarded as defective. But 'wild' EB virus recovered from the throat washings of IM patients has excellent transforming ability. It is clear, moreover, that the P3HR-1 virus does not induce a full lytic cycle in either the cord blood cell or the BJAB target, only short, abortive and suicidal stretches. It is also puzzling that the difference between the two virus strains is only apparent in relation to these target cells while in their own home strain both viruses seem to behave similarly. Both the B958 and the P3HR-1 cell lines have a proliferating, non-producer stemline, with occasional activation of the cycle in comparable, small numbers of cells. This is reminiscent of the lysogenic condition. Together with other evidence, for example differences in the producer status of foetal, newborn, adult and simian lines transformed by the same virus strain, this suggests that different lymphoid cells may vary in the degree of the restrictive control they can exert on a given virus strain. On the other hand, the P3HR-1-B958 virus comparison clearly shows that different virus strains may differ in the degree to which they obey the restrictions imposed by a given host cell. Somatic cell hybridisation experiments indicate that at least two different host cell controls are involved, one influencing the EA producing part and the other the late (viral DNA and viral capsid antigen producing) part of the cycle. Dominance of the more permissive character in the somatic hybrids suggests that both controls are of a positive nature.

The state of the viral genome in the transformed cells is of considerable interest. Nonoyama (University of Chicago) has reaffirmed his previous conclusion that at least a large part of

#### The Oklo phenomenon

from Peter J. Smith

In June 1972 a team of scientists from the French Atomic Energy Commission found that uranium samples from a mine at Oklo in the Republic of Gabon were depleted in uranium-235. In the first samples studied, the 235U content was only 0.003% down from the normal natural abundance average 0.720%; but more extensive work revealed that, in some samples, 224U accounted for only 0.40% of the total. Taking into account the total mass of the Oklo deposit, this meant that about 200 kg of ""U had apparently 'disappeared'-enough to produce about 10' megawatt-hours of ehergy in a nuclear power station and thus to power a moderate-size town for over 100 years.

The comparison with a power station is apt, for at a conference in Paris in September 1972 the French team proposed that the missing zisU had gone to fuel a natural reactor which had operated for a period of about 500,000 years some 1,800 million years ago. At that time, the 235U would have been more than four times as abundant as it is now. Neutrons produced by fission would be slowed down by environmental water, thus making them more effective in maintaining a chain reaction. Ultimately, however, the natural reactor would grind to a halt as the 235U burned up and as the surrounding water evaporated.

The reactor hypothesis is still unproven. But the issue may soon be resolved, for the French AEC has decided to release some samples of the Gabon uranium and its surrounding soil to the international scientific community. Some of the material has now been received by Dr S. A. Durrani of the University of Birmingham who plans to investigate the 'Oklo phenomenon' using thermoluminescence and fission track analysis techniques developed in connection with his study of lunar samples.

the viral genomes carried by non-producer cells exist in a free, plasmid-like form, although he could not exclude that some of the approximately 50 genomes could be covalently integrated with the host (Raji) cell genome. A. Adams Lindahl (Karolinska Institute) présented evidence for covalent integration, while she also confirmed that part of the genomes were free. The latter may be present in a circular form. Nonoyama also reported that he could reduce the multiple genome load of the Raji cell by cycloheximide

treatment. The state of the remaining genome has not yet been investigated.

While no restriction studies have been made on EBV as yet, Sugden (Karolinska Institute) reported the first EBV-transcription studies. He found a more extensive transcription of the viral genome (up to 30–50%) in the producer P3HR-1 line than in the non-producer Raji line, as expected. The viral RNA sequences detected in Raji cells were a subset of those found in P3RH-1 cells; they were sufficient to code for approximately 10 proteins. EBNA is the only known viral function in transformed non-producer lines.

**Immunological factors** 

Henle stressed the curious differences in antibody patterns between different EBV-associated diseases. Burkitt lymphoma patients with ongoing disease tend to form antibodies against one particular subcomponent of the early antigen complex (R). Mononucleosis and nasopharyngeal carcinoma patients preferentially make antibodies to another component (D). Since all known strains of EBV induce both antigens approximately simultaneously, during their cycle, these differences in the host response probably reflect the way in which the various antigens becomes available to the immune system. Considerable discussion followed the report of Henle that anti-EBNA antibodies appear very late, several months after the onset of infectious mononucleosis and are frequently low or absent in Hodgkin's disease (HD). Henle attributed this to the intranuclear nature of the antigen and postulated that considerable time is required before enough EBNA positive cells have been destroyed by the immune response. In HD the response would be often deficient.

The question why lymphoma, HD and other patients with EBV-genome negative tumours sometimes develop elevated EBV-antibody titres, approached by P. H. Levine and colleagues (National Institutes of Health). and by Johansson and colleagues (Karolinska Institute), respectively. Both dealt with the possibility that tumour-induced immunosuppression may be responsible, but in different ways. Levine found no evidence for any relationship between the lymphocytotoxicity reaction of Herberman against established lymphoma lines, and EBV titres. This reaction is mediated non-T lymphocytes, however. Johansson found a correlation between T-cell depression, as judged by PHA, Con A, and PPD lymphocyte stimulation or skin tests, and increased anti-EBV (VCA) titres. No such correlation was found with reactivity to a B cell mitogen (PWM). The notion that Tcell suppression may be crucial receives

support also from the demonstration by Aiuti that two congenitally T-cell deficient children had significantly elevated anti-EBV (VCA and EA) titres that fell to normal after thymus grafting and appearance of T cells in the circulation. It is likely that T cells play some regulatory part in maintaining the anti-EBV titre at a relatively low level from year to year in normal individuals. Depending on one's viewpoint, this could be attributed to T-cell mediated

#### Sabin withdraws claim

THE persistent irreproducibility and frustration to which Zur Hausen has alluded (see Klein on this page) is not confined to attempts to demonstrate herpesvirus DNA or antigens in cervical carcinomas. Albert Sabin has been obliged to withdraw his claim made early last year that a nonvirion antigen of HSV is associated with a large number of human cancers and can be found early in infection of guinea-pig cells in vitro (see Nature, 247, 334; 1974).

The history of frustration has extended over a period of five months during which Sabin has been trying to trace the reasons for his failure to reproduce the results he and Tarro reported last year (*Proc. natn. Acad. Sci. U.S.A.*, 70, 1032–1036 and 3225–3239; 1937). The irreproducibility of the results remains unexplained and Sabin's most recent paper (*Proc. natn. Acad. Sci. U.S.A.*, 71, 3248–3252, 1974) contains a detailed admission of defeat.

The difficulty in which Sabin now finds himself weakens the case for HSV as the aetiological agent of certain cancers; hopes of shedding light on oncogenesis through a study of the function of early HSV proteins are correspondingly dimmed.

surveillance against dormant, potentially neoplastic cells, or to some T-cell dependent antibody, acting either against dormant cells or against the spreading of periodically reactivated virus.

#### Marek's disease and herpes simplex

An important development in the field of Marek's disease is the establishment by Kato of three permanent lines which Nazerian has shown carry 70-80 genomes per cell. IUDR can activate antigen production in a small proportion of the cells. The lines had T-lymphocyte characteristics, confirming the suspicion that the disease is due to malignant T-cell proliferation. P. M. Biggs (Houghton Poultry Research Station) showed that bursectomy did not increase the incidence of the malignant lesion. Powell found that the

established lines can seve as targets for in vitro lymphocytotaicity tests. Preliminary evidence sugests that MDVinduced tumour cell may have a distinctive membrane antigen: clearly better antigen definition and immunological characterisation are urgently needed in the MD sysem. The disease seems to be uniquely sutable for studies on immune surveillante against tumours induced by a naurally occuring virus, with genetic differences in susceptibility and a corresponding contrast between self-limiting and malignant lesions. Biggs summarised the remarkable success story of vaccination against the malignant form, firs with attenuated MDV, and later with a partially crossreactive but non-pathogenic turkey herpesvirus (HTV). It is nteresting that without protecting birds from infection or reducing virus shedding the vaccine was nevertheless capable of preventing the development of malgnant disease. It is probable, although unproven, that this is due to immunisation against tumour-associated antigens. The situation may be analogous to the successful protection of hamsters noculated with polyoma or SV40 virus when newborn, by a second virus dose.

There is now increasing evidence that the HSV-transformed lines carry viral genomes. Frankel pointed out that viral RNA is often more easily detectable than viral DNA. Summers reported the detection of viral DNA using restriction fragments as the hybridisation probe.

Though laboratory models of HSV transformation have achieved a status of increased reproducibility, this cannot be said about the attempts to demonstrate herpesviral genomes or their antigenic footsteps in human cervical carcinomas. Zur Hausen said that this search has resulted in "persistent irreproducibility and persistent frustration, rather than persistent infection". This was countered by the argument that fractional genomes may be very difficult to demonstrate, as also evident from the in vitro transformed cell studies. The epidemiological evidence that links HSV type 2 infections to cervical carcinoma is circumstantial at best. While some careful studies suggest a relationship, at least in certain geographical areas and certain socioeconomic groups, the suspicion still prevails that the venereally transmitted type 2 infection may be another covariable of promiscuity, particularly the early onset of sexual life and multiple partners, factors that are known to have a role in the genesis of cervical carcinoma, rather than being an aetiological factor in itself. But recent epidemiological studies of the Melnick group where controls and cancer patients have been matched with regard to sexual history speak against this.

# Mutational pressure as the main cause of molecular evolution and polymorphism

Tomoko Ohta\*

The advent of detailed studies on the evolution of individual molecules has cast into doubt some of the neo-Darwinian concepts of what determines evolutionary change. Much more emphasis must now be placed on the constraints imposed by the structural and functional requirements of protein molecules, and on random fixation of very slightly deleterious as well as selectively neutral mutations.

As more data accumulate on evolutionary change at the molecular level, it becomes increasingly necessary to re-examine evolutionary theories<sup>1-4</sup>, and in particular the orthodox neo-Darwinian view that the rate and direction of evolution are determined almost exclusively by positive natural selection<sup>3-5</sup>. It is now clear that at the molecular level, evolutionary change results from the spreading of all 'tolerable' mutations in a population. But much of the theoretical argument depends on the definition of a tolerable mutation. Biochemists and non-population geneticists may equate the designation<sup>6-9</sup> with non-lethal, whereas to many population geneticists it means advantageous. There is, in fact, no clear distinction between tolerable and non-tolerable mutations: mutations occur continuously in any biological population, with a wide range of effects across the whole spectrum from lethal to advantageous.

Much recent evidence points to a continuum at one end of which are very nearly neutral mutations with undetectable phenotypic consequences, and at the other end of which are the mutations with a distinct phenotypic effect, and on which Darwinian selective pressures can therefore act. This point of view forms the basis for the present theory which can explain many of the recent data both on the rate of evolution as derived from studies of protein structure, and on the distribution of protein polymorphisms detectable as electrophoretic variants. Theoretically, it is possible to calculate the probability of fixation, or more generally the probability of mutants reaching a certain frequency within a population in terms of the "selection coefficient"10. If a mutant allele is selectively equivalent (neutral) to its wild-type allele, then the rate of mutant substitution in the population is equal to the mutation rate<sup>11</sup>. If the mutant is advantageous, the substitution rate is higher than the rate of mutational input and vice versa. Thus, tolerable mutations should include all those mutations which have a finite chance of survival, and the rate of evolution is determined by the average "selection coefficient" of new mutations 12,13.

This can be seen in the rate of evolution in various parts of the genome. It is now generally accepted that the less functionally rigid a molecule is the more rapidly it evolves<sup>5,6,9,14-16</sup>. For example, fibrinopeptides A and B and the middle segment of proinsulin are the fastest evolving molecules so far described and are enzymatically removed and discarded from the functional residue of the molecule<sup>5</sup>. The total genome DNA evolves at almost the same rate as these molecules<sup>17,18</sup>, which agrees with the proposal that the majority of genome DNA is not

informational in higher organisms<sup>15</sup>. This idea can be extended to the high variability of the "spacer" DNA of ribosomal genes19. Yet the evolutionary rate of fibrinopeptides may be slightly less than the mutation rate. This is because some structural constraint may affect polypeptide folding an so that the rate of evolutionary substitution of amino acids in fibrinopeptides is likely to be somewhat less than the intrinsic mutation rate. It is probable that molecular evolution proceeds essentially by mutational pressure rather than by positive Darwinian selection. More and more evidence is accumulating that the maximum observed evolutionary rate is close to the intrinsic mutation rates. If positive selection is the cause of such rapid evolutionary change, one must assume that, at any single period of evolutionary time, only a very few, specific, amino acid sites of a protein molecule can be replaced by definitely advantageous mutations. The remaining sites (constituting the majority) cannot accept mutations, since the fixation probability of definitely advantageous mutations can typically exceed 100 or 1,000 times that of neutral mutations in a large population. It is difficult to imagine that continuously changing environmental factors are so simple as to distinguish a few particular advantageous mutations among numerous others. Molecules are evolving individually, at a rate determined by the average selection coefficient of new mutations, which reflects the structural or functional constraints of each molecule. This view is essentially an extension of the neutral mutationrandom drift hypothesis of Kimura<sup>1</sup> and King and Jukes<sup>2</sup>, and takes into account the idea of "frozen accidents" proposed by Crick<sup>21</sup> and Ohno<sup>22</sup>. Once the structure and function of a molecule are determined in the course of evolution, natural selection acts mainly to maintain them, because all later evolutionary changes proceed under selective constraints. Natural selection then becomes mostly 'negative' and positive Darwinian selection is only a minor part of both total selection and the total number of mutant substitutions. If selection pressure is very weak, a mutant allele, even if slightly deleterious, can occasionally replace the original allele by random drift, particularly in small populations, and such chance events are likely to be important in molecular evolution 23, 24,

#### Higher order structures

Let us now discuss the effect of natural selection on secondary or tertiary structure, as natural selection acts through these higher order structures and not on primary structure. Probably the simplest example is the clover leaf structure of transfer RNA. I have suggested before that the coupled base substitutions in the paired region of this molecule, in the course

<sup>\*</sup>National Institute of Genetics, Mishima, Shizuoka-ken, 411 Japan.

of evolution, represent a very slightly deleterious base substitution in the first stage followed by a slightly advantageous complementary base substitution<sup>23</sup>. This hypothesis is supported by the observation of Holmquist *et al.*<sup>25</sup>. They have shown that G·U or U·G pairs account for about two-thirds of all non-Watson-Crick pairs in the helical regions of 43 sequenced tRNAs. They considered that since the presence of a single G·U pair does not interfere with helicity, it is an acceptable transitional stage. Other pairs such as A·C or G·A would cause greater distortion and therefore a mutation leading to such a change is less likely to spread in the population, and this non-random distribution of base pairs seems to fit the present hypothesis.

Transfer RNA is evolving at about the same rate as cytochrome c (ref. 25) and perhaps there is no fundamental difference between the evolutionary mechanisms of these two molecules. The molecular organisation of the secondary and tertiary structure of proteins is likely to be restored if another mutation is added after an amino acid is replaced in a well-organised system<sup>20</sup>. This is considered to be the basis of the observed linkage of amino acid substitutions.

This corresponds to Fitch's concomitantly variable codons (covarions)<sup>14</sup>. Wyckoff<sup>26</sup> by comparing bovine and rat RNases found that out of 18 changes which are involved in charge differences, about 14 are paired with respect to charge. Because of highly specialised intramolecular interactions<sup>27</sup>, the effect of the linkage of substitutions is apparently not the summation of the effect of each substitution. From these considerations, it is difficult to assess the adaptive significance, in ecological terms, of individual substitutions.

#### Selection pressure

Selection pressure must, in general, be very weak and indefinite for mutations that can only be detected at the molecular level, compared with mutations that have a visible effect. As neo-Darwinism is based on observations at the visible phenotypic level, it should be re-examined.

Consider a very small selective force as the lower limit of stronger selection. The majority of new visible mutations are deleterious, and the majority of "nearly neutral" mutations is likely to be very slightly deleterious, especially if the proteins and biochemical pathways are very highly organised and if environmental factors cannot interact directly with the primary structure of proteins. For such very slightly deleterious mutations, the chance of spreading by random drift is much higher in a small population than in a large population. In fact, if the product of the effective population number and the selection coefficient is less than unity, such mutations behave as if neutral and can spread through the population by random drift10. The product may be regarded as the number of effectively selected individuals per generation. This increases linearly with the increase of the total population size if the selective force is kept constant over a wide range whereas if the selective force is not constant, such a simple relationship may not hold<sup>28</sup>. As the product becomes larger, natural selection is more effective and very slightly deleterious mutations cannot spread23. Thus, the present hypothesis differs from the original neutral mutation-random drift hypothesis in emphasising a very small selection pressure. In fact, it is an extended form of neutral theory, conceived as the lower limit of the selective process.

Through extensive studies using *Drosophila melanogaster*, Mukai has shown that the mutation rate of viability polygenes is about 0.3 per genome per generation—much higher than previously thought<sup>29,30</sup>. This rate applies to those mutations which have effects strong enough to be detected by Mukai's viability test. If there is continuity of mutational change from disadvantageous to neutral, one would expect substantial numbers of nearly neutral mutations. Let us tentatively estimate the informational genome size of *Drosophila* from Mukai's

result. If the intrinsic mutation rate per base pir per generation is roughly  $10^{-8}$  as previously estimated<sup>5,15i1</sup>, then viability polygenes should correspond to  $3\times10^7$  bas pairs, and this amounts to one-third of the genome DM. Furthermore, if the total gene number in *Drosophila* is abot 6,000 (ref. 32), the average gene size becomes 5,000 base airs. Genes may include much of the regulatory DNA and the lass of mutations whose effects are not large enough to be deteted by Mukai's test. The latter class probably includes important candidates for "tolerable mutations". In my view, thee should be no distinct borderline between deleterious and neutral, between deleterious and advantageous, or even between deleterious and overdominant mutations. Random genetic drift and mutational pressure play a much bigger part than has been telieved.

#### Molecular polymorphisms

Mutational pressure is also important for the maintenance of molecular polymorphisms. Electrophoretically detectable alleles show a remarkably uniform distribution over a very wide geographical range in Drosophila33. This observation has been explained by the neutralists assuming migration34-36, whereas selectionists attribute it to some forms of "talancing selection"33,37. Very recently, by combining heat-denaturation studies with electrophoresis, Bernstein et al.38 lave found that each electrophoretic allele can be divided irto a few heat sensitive alleles at the xanthin dehydrogenase ocus in Drosophila. Their data, although not yet conclusive tecause of small sample sizes, suggest that these minor components within an electrophoretic class are geographically differentiated. They argue that electrophoretic alleles are maintained by balancing selection while heat-sensitive alleles may be selectively neutral. It is hard to imagine, however, particularly in the light of recent knowledge of protein structure and function27, that natural selection makes a clear-cut distinction between these two classes. It is more likely that genetic variabilities detected by electrophoresis in large populations like those of Drosophila represent a mutation-selection balance. For minor components (heat-sensitive alleles within each electrophoretic class), stochastic effects due to random drift are more prominent because of lower mutational input, and hence they may be geographically differentiated. Of course urgent investigation is needed to find out if the pattern observed by Bernstein et al. represents a general phenomenon.

So far, observations on protein variations in natural populations have been based mainly on protein electrophoresis<sup>39</sup> which only detects mutations which express themselves as charge differences on the molecule. To analyse such variations, therefore, we proposed a model of stepwise production of alleles in which the entire allelic states are expressed by integers, and mutations are represented by moving each allele one step either in the positive or in the negative direction on the allele space<sup>5,40</sup>. On the basis of this mutational scheme, we have investigated the theoretical consequences of weak negative selection (T. O. and M. Kimura, unpublished). In a typical example, we assume one type allele and multiple slightly deleterious mutations as follows:

mutation . . . 
$$v/2$$
  $v/2$   $v/2$   $v/2$   $v/2$  . . . allele . . .  $A_{-2} \rightleftharpoons A_{-1} \rightleftharpoons A_0 \rightleftharpoons A_1 \rightleftharpoons A_2$  . . . fitness . . .  $1-s$   $1-s$   $1$   $1-s$   $1-s$  . . .

where  $\nu$  is the mutation rate per gamete per generation and s is the selection coefficient assuming genetic selection. Under this model, it can be shown that the mutation-selection balance predominates if the product of effective population size  $(N_e)$  and mutation rate  $(\nu)$  is sufficiently large provided that  $s > \nu$ . The distribution is determined by the ratio  $s/\nu$  and the results conform quite well to the observed pattern of allelic distribution, that is, the commonest allele is surrounded by less common or rare alleles. Now, if population size becomes small so that  $N_e s$  is smaller than unity, very slightly deleterious alleles

become effectively neutral and the heterozygosity is determined by  $N_{ev}$  (ref. 41).

We have already suggested from a comparison of actual observations with the results of our simulation experiments assuming stepwis production of neutral alleles, that there are more rare allele than predicted from the strictly neutral hypothesis41. If we bring very slight negative selection into the model, the dscrepancy between the observation and the simulation should disappear completely. Perhaps the recent analysis of Yamizaki and Maruyama<sup>42</sup> needs re-examination in the light of ths. From data on protein polymorphisms, they found that the observed frequency of heterozygosity as a function of gene frequency follows a roughly uniform distribution in the range 0.0~0.5 (because of folding back the distribution around 0.5 (ref 43). They used data on several hundred electrophoretic allele and because the observed distribution agrees with Maruyama's theoretical prediction<sup>43</sup>, concluded that their analysis supports the selective neutrality of protein polymorphisms. If one uses the model of stepwise production of alleles by mutation, however, the distribution of the frequency of heterozygosty is not uniform unless  $N_e v$  is extremely small, even if alleles are neutral. Through an extensive Monte Carlo experiment assuming the step-allele model and selective neutrality, I have found that the frequency of heterozygosity gradually increases as the gene frequency class moves from 0.0 to 0.5 for the actually interesting range of  $N_{ev}$  (0.05 ~ 0.5). The observations on isozyme polymorphisms thus indicate once again the existence of more sporadic alleles than predicted by strict neutrality

#### Uniformity across species

A further argument against Darwinian selection as the sole determinant either of evolution or of polymorphism can be made on the basis of the remarkable uniformity of evolutionary rate and of heterozygosity between species. Individual cistrons seem to evolve at a very similar rate in diverse lines of organisms<sup>6,7,11,14,16</sup>. The existence of some local variations in evolutionary rate in closely related species12 does not materially affect the validity of this general statement<sup>3,5,44,45</sup>. If the majority of amino acid substitutions is due to positive Darwinian selection in response to environmental changes, one has to assume that such changes occur at roughly the same rate in various different lineages. It is hard to believe, for example, that the carp and the human lineages have experienced similar rates of environmental change. Similar arguments apply to the uniformity of the average heterozygosity per locus in different species. While this uniformity does not follow from the neutral mutations hypothesis, which predicts an indefinite increase in heterozygosity with increasing population size, it fulfils the expectations of selectionist hypothesis no better. Escherichia coli, for example, has an immense population size by comparison with Drosophila or man, and an entirely different ecology, but approximately the same degree of 'heterozygosity' in terms of effective number of alleles46

Approximate uniformity in the rate of evolution is to be expected if evolutionary change proceeds essentially by mutational pressure. The uniformity in heterozygosity between species can most plausibly be explained in terms of a balance between mutational and selective pressures. In a large population, heterozygosity is close to the maximum that can result from mutational pressure balanced against selection based on the structural and functional constraints of the molecules themselves. The constraints imposed by the structural and functional requirements of the peptides are taken as almost independent of ecological conditions<sup>20</sup>. The importance of such structural constraints is illustrated by the observation<sup>47</sup> that there is less heterozygosity for glycolytic enzymes than for other proteins, since the glycolytic enzymes might be expected to have the more rigid functional requirements<sup>48</sup>. If similar

distinctions are not seen in some mammalian species\*, this may be because they have not yet arrived at a mutation-selection equilibrium.

#### Enzyme differentiation and speciation

The patterns of enzyme differentiation between sibling species in the Drosophila willistoni group50 can most readily be explained by assuming that they have reached a mutation selection balance. The patterns of allelic variation in this group fall into two classes: (i) sibling species with the same set of alleles in similar frequencies; (ii) sibling species with non-overlapping allele distributions. For loci belonging to the first category, the same mutation-selection scheme applies to both sibling species, whereas for those in the second category, I suggest that the balance has shifted at the molecular level in the course of speciation. In a well adapted species, a constant input of very slightly deleterious mutations does not result in the replacement of the original allele if the population is very large. In small populations, which may often occur at the time of speciation, very slightly deleterious mutations behave as effectively neutral and may replace the original allele by chance. Then molecular constraints will be shifted, leading to a new mutation-selection balance. Thus, the degree of neutrality of new mutations is crucial to my theory of what determines the rate of evolutionary change and speciation. If the borderline cases between slightly deleterious and completely neutral mutations are important, as I assume here, then the population size becomes most crucial and the rate of evolution is higher in small populations such as may occur at the time of speciation. It is suggestive that the amino acid substitutions seem to be concentrated at the branch points in the phylogenetic trees of cytochrome c and the haemoglobins  $^{51-53}$ . This tendency, however, may be a statistical artefact resulting from the assumption of maximum parsimony which leads to the postulation of hidden mutational substitutions. The true pattern of molecular evolution and variation can only emerge from further investigation, bearing in mind particularly the importance of intramolecular organisation which derives from the polypeptide folding mechanism. It is this that determines molecular function and hence is subject to natural selection, and here ecological conditions are likely to be much less significant than has traditionally been supposed. In the light of such considerations, the original concept of the integrated gene pool<sup>54</sup> may have to be modified.

Finally, the distinction between the strict neutral theory and my theory should be clarified. (i) The neutral theory classifies new mutations into discrete classes; deleterious, neutral and advantageous classes. In my theory, there is no clear-cut distinction among these classes and the borderline cases are assumed to be more important. (ii) The rate of amino acid substitution is higher in small populations in my theory, whereas it is independent of population size in the strict neutral theory. Consequently, my theory predicts that substitutions will be concentrated at the time of speciation, when small population size creates a "bottle neck". (iii) In very large and stable populations, my theory gives an upper limit for heterozygosity.

I thank Dr M. Kimura for discussions and encouragement.

### Sequence analysis of immunoglobulin light chain messenger RNA

C. Milstein, G. G. Brownlee, E. M. Cartwright, J. M. Jarvis & N. J. Proudfoot

Medical Research Council, Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

RNA and DNA sequencing methods are used to define some features, principally at the 3' terminus, of the structure of immunoglobulin light chain mRNA. The results show that there is one molecule coding for the V and C regions of the light chain and rule out the possibility of two separate molecules.

A DETAILED knowledge of the structure of messenger RNA is required for a full understanding of its function, to define not only its coding properties but other less well known properties, such as control signalling and transport. For this, the sequence of those parts of the mRNA not coding for protein—the untranslated regions—is of special importance. Until recently, technical difficulties have confined such studies to bacteriophages. But a start has now been made on the structure of the eukaryotic mRNA coding for immunoglobulin<sup>1</sup> and globin<sup>2-5</sup>. The structure of the immunoglobulin mRNA is particularly important because of its relevance to basic problems of immunology. Light and heavy Ig chains contain a variable region (V region) which defines the antibody specificity and a region which is constant for each type and class of chain (C region). It is believed that the chains are coded by separate pools of V and C genes and that each chain is the result of the expression of a single gene from each pool<sup>6</sup>. To determine the number of genes involved in each pool by hybridisation techniques, a knowlege of the structure and purity of the mRNA is required. In addition the critical question of whether the integration is achieved at the DNA, RNA or protein level has been the subject of considerable speculation. A number of experiments indicated that the chains were synthesised from a single mRNA molecule rather than from two<sup>7-9</sup>. Objections, however, have been raised and direct structural evidence is essential to settle finally the argument.

In this paper we present further sequence studies on the light chain mRNA of the mouse myeloma, MOPC 21. We describe the sequence and location of the larger T<sub>1</sub> RNase oligonucleotides within the mRNA, and the sequence of 52 nucleotides adjacent to the poly (A.) These are included within a region of about 200 untranslated bases in the 3' terminal position. Overall the results establish the presence of a single molecule involved in the synthesis of both V and C regions.

Nature Vol. 252 November, 29 1974

Characterisation and location of larger T<sub>1</sub> endproducts

Methods for puriving light chain mRNA have been developed by ourselves<sup>1,10</sup> and others<sup>11–13</sup> for a number of different mouse myelomas. The furity achieved is difficult to assess because of the different critria used by different workers. We have consistently used cells which have been grown in tissue culture because they repesent a much better starting material than the

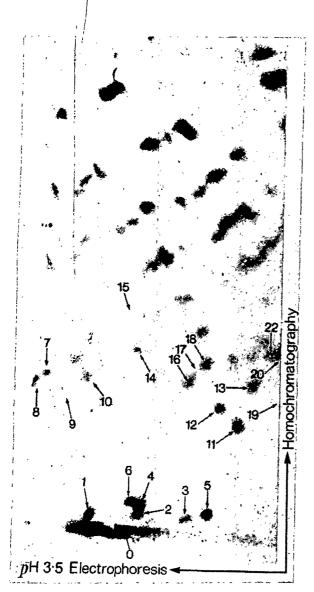

Fig. 1 Two-dimensional fractionation of a T<sub>1</sub>-RNase digest of <sup>32</sup>P-labelled light chain mRNA, purified from microsomes by successive sucrose gradient centrifugation and dT-cellulose chromatography¹ and finally by acrylamide gel electrophoresis in 8 M urea¹º. Fractionation in direction 1 is by ionophoresis at pH 3.5 in 7 M urea using cellulose acetate ('Cellogel'); direction 2 is by homochromatography on DEAE-cellulose thin layers (1:7) using a 3%, 10 min hydrolysed nucleic acid mixture. The numbered spots were eluted and analysed by further digestion with pancreatic RNase. We were unable to use these fingerprints for more detailed sequence studies as the radioactivity in the oligonucleotides was insufficient. To prepare oligonucleotides with enough radioactivity for further analysis, a less pure preparation had to be used in which the last step of purification was omitted. Fingerprints of the 30-50% pure mRNA were more complex but all the spots numbered in the figure could be clearly identified. They were eluted and analysed by further digestion with pancreatic RNase and separately by digestion with U<sub>2</sub>-RNase¹8. Spot 21 is not shown here but runs just to the right of, and midway between, spots¹19 and 20 (see Fig. 3). Spot 0 is unresolved from the streak at the origin (poly(A)) here. It was resolved in other experiments by using a stronger homomixture (5% unhydrolysed) in the second dimension.

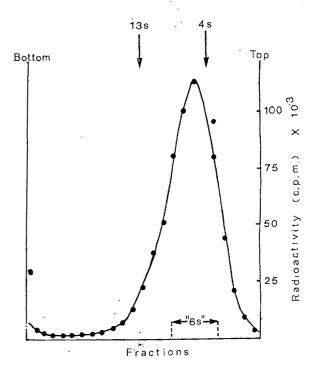

Fig. 2 Sucrose density gradient centrifugation of partially hydrolysed light chain mRNA. About 1 μCi of <sup>32</sup>P-labelled mRNA (30-50% pure material) was incubated for 25 min at 40° C in the presence of 50 mM Na<sub>2</sub>CO<sub>3</sub> and 40 μg yeast RNA. After addition of 3% SDS, 10 mM Tris Cl (pH 7.0) and 5 mM EDTA and incubation for 5 min at 70° C the fragmented RNA was fractionated in 15-30% sucrose density gradients in 100 mM NaCl, 5 mM EDTA, 10 mM Tris Cl (pH 7.6) and 0.5% SDS in the MSE 6 × 14 ml swinging rotor (35,000 r.p.m. for 17 h at 30° C). A peak of radioactivity (6S) was poled and fractionated by dT-cellulose chromatography. The poly(A)-containing fraction (20% of the total) was precipitated with ethanol and subjected to fingerprint analysis (see Fig. 3). 4S is the position of an internal unlabelled marker of E. coli tRNA and 13S that of intact (unhydrolysed) mRNA run in a parallel gradient.

more generally used solid tumours grown subcutaneously in mice. Furthermore, the tissue-cultured cells are ideal for the preparation of <sup>32</sup>P-labelled mRNA, which is then suitable for purity studies by chemical characterisation. Chemical methods are a necessary complement to purity determination based on less reliable procedures such as homogeneity on separation systems or specific translation in heterologous cell-free systems.

In a previous report<sup>1</sup> we described the preparation of purified light chain mRNA. Four oligonucleotides, ranging in size from 19-22 bases in length, were isolated from partially purified light chain mRNA and aligned with specific regions of the amino acid sequence of the protein. These four oligonucleotides-and others, described below—were prominent spots in T<sub>1</sub>-ribonuclease fingerprints, but were superimposed over an obvious background of spots presumed to derive from contaminating mRNA. We were then able to use these assigned oligonucleotides as chemical markers for the presence of light chain mRNA. Further purification was achieved by acrylamide gel electrophoresis where four bands were resolved. The light chain mRNA was identified as the only band containing the marker oligonucleotides in T<sub>1</sub>-ribonuclease digests. Evidence of purification was also provided by the much lower level of background oligonucleotides in the fingerprint.

Figure 1 is an example of a fingerprint of light chain mRNA purified by acrylamide gel electrophoresis showing the marker oligonucleotides (spots 2-5), with only a very faint background of contaminating material, and many other products in yields equimolar<sup>10</sup> to the markers, as would be expected from a pure molecule of the size of 13S. These additional oligonucleotides must, like the markers, derive from the mRNA and all those

<sup>\*</sup> Sequences were derived from results of both the pancreatic RNase and the U2-RNase end products of each spot1 and dignment with a predicted sequence derived from the known amino acid sequence. Where only partial sequences are shown, the products of ancreatic RNase digestion are listed. In these cases the quantitative values are only approximate. Two oligonucleotides (not marked on Fig. 1) both between 10 and 15 bases long, were not included in the table because of incomplete sequence information.

V, C and X show the alignment of the oligonucleotide with either the variable (V), constant (C) or neither (X) region of the mRNA. (3)

shows that the nucleotide was in the 3' untranslated region (see Fig. 3).

† The sequence of 8 and 11 b was deduced solely from the sequence analysis and independently of the protein sequence. § Previously characterised¹.

longer than nine residues, as well as some smaller ones, have now been studied (Table 1). Of these, 16 (including the four previously characterised) are assigned to the coding regionfive corresponding to the V region, 10 to the C region, and one (11 b) to the link or 'switch' between V and C. This sequence corresponds to residues 105-108, as follows:

105 Glu Ile Lys Arg (G)AA AUA AAA CG

These are residues that are generally considered to be in the V region, except for the arginine which could be described as the first of the C region. Nine oligonucleotides (Table 1) did not fit with any of the sequences predicted by the protein sequence and should therefore belong to the untranslated region. If so, they should be located either at the 5' or the 3' end of the molecule. To investigate this problem we introduced a small number of random breaks in the intact mRNA by means of mild alkaline digestion. Then, the fragments of a given size range were fractionated by oligo (dT)-cellulose chromatography (Fig. 2). In this way, the segments of mRNA which remained attached to the poly(A) (3' end of the mRNA) could be investigated by fingerprinting. The relative simplicity of this fingerprint (Fig. 3) showed that the fractionation was specific, and the presence of poly(A) that it derived from the 3' end. A further indication of the simplicity of the fingerprint was the separation observed in the region of the smaller oligonucleotides (top of the fingerprint). Thus spots 51 and 52 were resolved from the background, whereas in the intact mRNA they were unresolved from other components of related sequence. The numbered oligonucleotides (Fig. 3) were characterised by digestion with pancreatic ribonuclease. Almost all of the nucleotides assigned to the untranslated region (1, 6, 7, 8, 11a, 12a and 21, but not spot 0, and possibly one of the components of 12, see Table 1) were present in the fingerprint, but the oligonucleotides assigned to the coding region (for example 2, 3 and 5) were absent or present only in very low yields (see below). Thus all the main components are located between the coding region and the poly(A).

The above results suggest that there is a considerable number of bases in the 3' untranslated region. A simple addition of the lengths of the oligonucleotides 1, 6, 7, 8, 11a, 12i, 21, 51 and 52 gives a value of 106-108 residues. This excludes all the oligonucleotides shorter than hexanucleotides and therefore is obviously an underestimate. Thus in the sequence of 52 residues immediately adjacent to poly(A) (see below) 13 residues in digests of T1 RNase occur as small oligonucleotides. If we include these we account for 120 residues. That leaves the other small oligonucleotides of Fig. 3, which at a conservative estimate make the minimum total up to 150 bases in the 3' untranslated region.

An alternative method for estimating the length of the 3' untranslated region was based on the measurement of the molecular weight of the 6S preparation. This ranged evenly from  $0.7 \times 10^5$  to  $1.7 \times 10^5$ , as determined by acrylamide gel electrophoresis in formamide<sup>1</sup>. We calculated, therefore, that the 6S fraction is a mixture of fragments varying in size from 220 to 530 bases. In a population of molecules such as this the relative yields of oligonucleotides in a T<sub>1</sub> ribonuclease digest will be inversely proportional to their distance from the poly(A) at the 3' end. An examination of Fig. 3 shows that most of the spots in the coding region of the mRNA are completely absent, although three spots, 18, 19, and 4, are present in low yield. These correspond to residues 208-211, 196-199 and 200-206 respectively of the light chain. The largest fragments of the 6S fraction, therefore, include about 60-80 bases corresponding to the last 20-25 amino acids of the light chain. Subtracting this figure from the longest fragments in the preparation (530), we calculate that the 3' untranslated region is about 450 bases long, including the poly(A). Assuming that the poly(A) is still 200 bases long (in these longest fragments), the length of the 3' untranslated region is about 250 bases. This length measurement is critically dependent on the accuracy of the molecular weight determination and on our ability to recognise marker oligonucleotides. Spots present in less than 10% yield of the major spots on the fingerprint of Fig. 3 are probably not detected.

Two oligonucleotides are present as a mixture and may be distinguished by their different 3' ends after U2-RNase digestion. At least one is assigned with the 3' untranslated region.

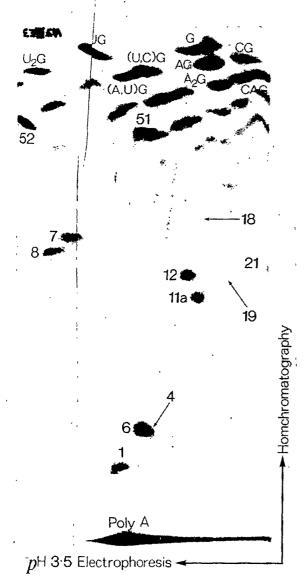

Fig. 3 Two-dimensional fractionation of a T<sub>1</sub>-RNase digest of the poly(A)-containing 6S fraction isolated by partial alkaline hydrolysis (Fig. 2). Fractionation was as in Fig. 1 except that a stronger 'homomixture' (5% unhydrolysed) was used for the second dimension. Spots were numbered from their position by comparison with Fig. 1, eluted and their identity confirmed by further digestion with pancreatic RNase. Spots 4, 18 and 19 were in too low yield for this check to be made. Spots 51 and 52 are relatively small oligonucleotides not isolated in intact mRNA. Their pancreatic products indicated that they were (A-C, U<sub>2</sub>, C) G and (U<sub>4</sub>, C) G respectively. The structure deduced for other smaller spots is shown directly.

This would give an overestimate of the length of the 3' untranslated region and 250 bases is likely to be a maximum value.

Despite the discrepancy in the values obtained (150 and 250 residues) we have argued that the lower value is an absolute minimum and the upper value probably a maximum value. Taking an average, we conclude that there are 200  $\pm$  50 bases present in this region.

Sequence of 52 bases adjacent to poly(A)

An alternative approach to sequencing the 3' end of the mRNA involves the use of the reverse transcriptase activity of DNA polymerase I from Escherichia coli<sup>2,5</sup>. With an oligo(dT)<sub>12</sub> as primer, synthesis of complementary <sup>32</sup>P-labelled DNA (cDNA) starts at the poly(A) or 3' end of the mRNA. Thus (<sup>32</sup>P) CTP-labelled cDNA was prepared using light chain mRNA

digested with endonuclease IV and fractionated (Fig. 4). The fingerprint obtained was highly characteristic (see legend to Fig. 4). The seven oligonucleotides numbered 1-7 (and two other spots—8 and 9—which were obtained from [a-32P] GTP-labelled cDNA) were sequenced using the techniques of partial exonuclease digestion, depurination and nearest neighbour analysis 15,16, to give the DNA sequence shown in Fig. 5. A comparison of this sequence with the results discussed in the previous section shows that it is complementary to some of the larger T<sub>1</sub> oligonucleotides shown to be in the 3' untranslated region of the mRNA (spots 6, 8, 51 and 52 of Table 1). Thus we conclude that DNA polymerase must be synthesising an accurate complementary sequence. The mRNA sequence may be drawn in the form of a double hairpin loop by maximising the extent of base pairing. The resultant structure is shown in Fig. 5a of the accompanying article5, where a comparison with a related region in rabbit β-globin mRNA is presented and discussed.

Fig. 4 Two-dimensional fingerprint of an endonuclease IV digest of (32P) dCTP transcript of immunoglobulin light chain mRNA. The mRNA preparation was contaminated with DNA. Therefore it was heated to 100° Cfor 5 min and digested with pancreatic deoxyribonuclease (0.2 mg ml-1) in 10 mM Tris chloride pH 7.5 and 10 mM MgCl<sub>2</sub> at 37° C for 30 min. EDTA was then added to 20 mM, the solution taken to 95° C and mRNA extracted using a phenol chloroform mixture (50:50) at pH 9.0. The RNA was concentrated by ethanol precipitation and transscribed using the Klenow subfragment of DNA polymerase I (E. coli) and Mn<sup>2+</sup> with [α- <sup>32</sup>P] dCTP (specific activity 100 Ci mmol<sup>-1</sup>,) and dATP, dGTP and TTP. The cDNA was isolated and then subjected to endonuclease IV digestion as described in the accompanying article<sup>5</sup>. Spots 5 and 6 were more prominent in other experiments. The unmarked prominent components near the origin of the second dimension are due to incomplete digestion by the endonuclease IV. In addition there is a complex background of weaker spots. Some are known to represent minor digestion products, while others are uncharacterised but may be due to longer cDNA copies or to transcripts of contaminating mRNA or DNA.

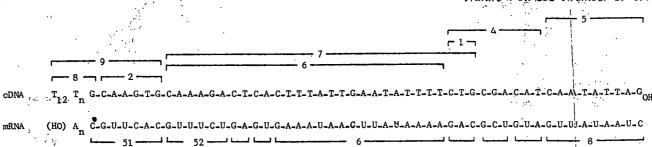

Fig. 5 Sequence of cDNA transcript of mRNA. The numbers above the sequence refer to the products of endonucless IV digestion shown in Fig. 4. The positions and sequences of the complementary T<sub>1</sub> oligonucleotides (Fig. 3 and Table 1) to this squence are as shown below the sequence. It should be noted that there is no formal overlap between the endonuclease IV spots 2 and 6 on the one hand and 4 and 5 on the other hand. The arrangement shown was established by the kinetics of labelling of the cINA.

Implications of the structural studies

A unique sequence of 52 bases has been established for the 3' end of the mRNA immediately adjacent to the poly(A). This is included within a region of 200 ( $\pm$  50) bases located between the coding region and the poly(A). In addition, a catalogue of 25 oligonucleotides ranging from eight to about 45 bases long is presented, and accounts for about 345 residues or one third of the length of the mRNA (excluding the poly(A)). Of these, 194 bases have been assigned to the coding region accounting for 75 amino acids out of a total of 214 of the light chain. From these results we can now propose a simple outline diagram (Fig. 6a) for the mRNA defining the approximate lengths of the various regions. Of particular interest are the 3' and 5' untranslated regions (3' and 5' UT in Fig. 6). The length of the 3' UT (200 bases) is probably accurate to within 50 bases, but that of the 5' UT region (150 bases) is much less accurate as it was derived by difference and is subject to the errors in all the other determinations1. A knowledge of the extent of the 3' UT region is critical to experiments in which complementary DNA is used for hybridisation with cellular DNA, designed to determine the number of V and C genes17. The function of such a long 3' untranslated region remains unknown.

Figure 6a shows the presence of V and C regions within a single mRNA molecule. An alternative model in which the V and C regions occur on separate molecules-illustrated in Fig. 6b—deserves special consideration in view of the existence of separate V and C genes. In both models we have used a length of 1,250 bases for all molecules because this is the size of the mRNA from which oligonucleotide markers for both regions have been isolated (see Table 1). Model b predicts that there should be two separate sequences for the two 3' UT

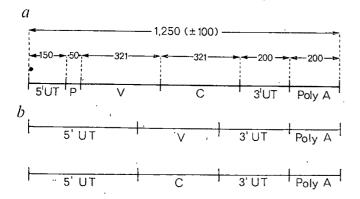

Fig. 6 Diagrammatic representation of the MOPC 21 light chain mRNA. a, Arrangement of the various regions and their length in numbers of bases. The lengths of the V (variable) and C (constant) regions are derived from a knowledge of the protein structure. The length of the 3' untranslated region (3' UT) is discussed in the text while that of the poly(A) and of the total mRNA is taken from ref. 1. P: precursor region<sup>19</sup>. b, Hypothetical alternative arrangement of V (variable) and C (constant) regions on two different mRNA molecules (see text).

regions. We have only found one such region the 52 residue long sequence shown in Fig. 5. Nevertheless, it ould be argued that the two mRNA molecules depicted in Fig. 6b have identical 3' untranslated sequences. If this wereso, the yield of oligonucleotides derived from the two regions hould be twice that of those nucleotides present in either the Vor the C region. The relative yields of some of the large T<sub>1</sub> olionucleotides of Table 1 have been measured<sup>10</sup> and are as follows: Spot 1 = 1.0; spot 2 = 1.3; spot 3 = 1.0; spot 4 = 1.1; spot 5 = 1.2; spot 6 = 0.8. It is clear that the yields of spot: 1 and 6, which derive from the 3' UT region, are equimolar witlin experimental error with those of various markers in the coding region (spots 2-5). Thus, the data contradicts the model. Inaddition, model b predicts that there are over twice as miny residues in untranslated regions of the mRNA as in the coding regions. Table 1 shows that 194 bases have been assigned to the coding region compared with 118 in the untranslated region. These figures again contradict model b, but lend support to model a. A 'switch' oligonucleotide spanning residues 105-108 of the amino acid sequence (spot 11b of Table 1) was isolated. Although this overlap of the V and C regions is rather too short to be considered as independent evidence for a single mRNA molecule it is fully consistent with it. Thus the structural studies reported in this paper confirm the hypothesis that there is a single mRNA molecule containing the sequence information for both the V and C regions of the light chain protein.

### Sequence at the 3' end of globin mRNA shows homology with immunoglobulin light chain mRNA

N. J. Proidfoot & G. G. Brownlee

Medical Researd Council, Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

The sequence of 52 nucleotides adjacent to the poly(A) of rabbit \beta glolin mRNA has been determined. Striking sequence and structural homologies exist between it and mouse immunælobulin light chain mRNA. These homologies may be common to all mammalian mRNA.

THE messenger RNA (mRNA) coding for globin is an obvious choice for detailed sequence determination. It is easily purified and can be obtained in good yield1.2. All the mRNAs that have been purified including globin mRNA, are known to contain more nucleotides than are required for coding3. These extra residues, presumably present on each side of the coding region, and defined as the 5' and 3' untranslated regions, are of unknown function. They must, however, include control elements, presumably deined by nucleotide sequence. Functions such as translational control, the termination of transcription, the addition of poly(A), the binding of transport proteins and mRNA degradation are likely candidates.

Although globin mRNA has been available in a purified form for several years, the determination of its sequence has not been seriously attempted. RNA sequencing by radioactive techniques has been successfully applied to transfer, ribosomal and viral RNA'species, but has not been extensively used for mRNA because of its size and the difficulty of labelling it in vivo3. We report here the use of a new approach that overcomes these difficulties. Instead of labelling the mRNA strand in vivo, a radioactive DNA copy is synthesised by means of an RNA-dependent DNA polymerase. Reverse transcriptase, from various sources is well known to be active in this synthesis, but we have used, in preference, the reverse transcriptase activity of DNA polymerase I of E. coli which is very active in the presence of low concentrations of manganese4. An advantage in using a DNA polymerase is that synthesis starts only from a double stranded region. Such a region is defined at the extreme 3' end of the mRNA by hybridisation of oligo dT to the poly(A). Also, recent work in this laboratory<sup>6,8</sup> has established elegant procedures for the sequence analysis of radioactive DNA.

Globin mRNA sequence

Radioactive complementary DNA (cDNA) was prepared using each  $[\alpha^{-32}P]$ -labelled deoxynucleoside triphosphate of high specific activity in turn and the other three unlabelled triphosphates, with DNA polymerase and manganese. The conditions of incubation were identical to those previously described4 except that a subtilisin fragment of DNA polymerase I was used5, which lacks the 5' exonuclease activity of the enzyme. In these conditions short cDNA transcripts, about 50 nucleotides in length, were synthesised. The <sup>32</sup>P-cDNA was purified and digested with endonuclease IV (refs 6 and 7)

followed by two-dimensional fractionation (Fig. 1). The oligonucleotides thus separated were sequenced using the techniques of partial exonuclease digestion, depurination and nearest neighbour analysis6,8.

A detailed account of this work will be presented elsewhere, but as an example of the techniques that were used the fractionation of a partial venom exonuclease digest of spot 9 is shown in Fig. 2. The sequence of this oligonucleotide was tentatively deduced from the relative mobility of the spots8 giving the sequence as shown in the figure. Partial digestion with both venom and spleen exonucleases were particularly useful techniques. Once a successful digest and fractionation was obtained, as in Fig. 2, it was relatively straightforward to confirm the postulated sequence by using the standard methods of depurination and nearest neighbour analysis, with each of the four input labels. In this way, all the endonuclease IV products, except the very large ones close to the origin of the second dimension, were uniquely sequenced.

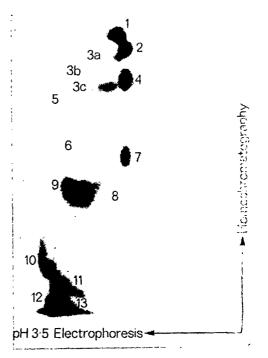

Fig. 1 Two-dimensional fingerprint<sup>22</sup> of an endonuclease IV digest of the cDNA of rabbit globin mRNA. [a-<sup>32</sup>P]-GTP-labelled cDNA<sup>4</sup> was purified by pancreatic digestion (10 µg ml<sup>-1</sup> pancreatic ribonuclease at 37° C, 30 min) followed by phenol extraction with a phenol-chloroform-isoamyl alcohol mixture (50:50:1) several times. The aqueous layer was ethanol precipitated, acid precipitated and dissolved in 30% triethylamine carbonate pH 10.0. Finally the triethylamine carbonate was removed by freeze drying with distilled water washes. The sequences of the spots are identified in Fig. 3.

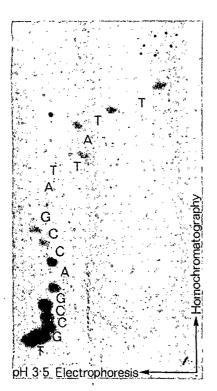

Fig. 2 Two-dimensional fingerprint<sup>22</sup> of a partial venom exonuclease digest<sup>6</sup> of spot 9. The sequence (5') - T-T-A-T-T-A-G-C-C-A-G-C-C-G-T (3') was deduced from the relative mobilities of the intermediates and confirmed in further experiments.

The final sequence was obtained by overlapping the sequenced oligonucleotides. This proved to be relatively easy, as amongst the oligonucleotides of Fig. 1 were larger products of partial digestion with endonuclease IV. Analysis of these products using depurination and nearest neighbour analysis gave the unambiguous sequences shown in Fig. 3. The overlap with the oligo  $dT_{12}$  was facilitated by a knowledge of the tetranucleotide sequence adjacent to the poly(A) in  $\alpha$  and  $\beta$  globin mRNA previously reported. The main overlapped sequence derives

from the higher yield oligonucleotides in F. 1. Some lower yield products, however, notably 5, 6 and 7 are unaccounted for in this sequence.

A problem in sequencing globin mRNA that, as usually isolated, it is a mixture of both a and B mNA, as may be shown by translation experiments in heterlogous cell free systems. From the sequence results described bove it seemed likely that our particular preparation of glbin mRNA, by contrast, contained predominantly one of th mRNA species (either  $\alpha$  or  $\beta$  globin mRNA) and relatively life of the other. To establish the identity of the major sequere, the mRNA preparation was assayed by translation in wheat germ extract. Characterisation of the 35S-methionine-ibelled product by the analysis of the labelled tryptic peptide showed that 5-10 times as much β globin as α globin was inthesised. We conclude that our mRNA preparation containspredominantly β globin mRNA and that this is the source of the major (52) sequence. Although the minor sequence of te a globin is incomplete, homology between the a oligonuclotides and the β mRNA sequence is apparent (Fig. 3).

#### Hairpin-loop structures

Figure 4 shows the  $\beta$  globin mRNA sequence complementary to the  $\beta$  globin cDNA) drawn in the form f two possible hairpin-loop structures, maximising the extent of base pairing. The stability of the hairpin loops may be assessed and the longer hairpin loop (labelled II in Fig. 4) has large negative free energy ( $\Delta G$  (25° C) = -10 kcalorie), suggesting that it is a stable entity. The smaller hairpin loop has ither zero free energy (Ia) or a value of +4 kcalorie (in Ib), suggesting that it is thermodynamically unstable.

In spite of this, we suggest that a double hairpin-loop structure exists and that it is stabilised by interactions with other parts of the mRNA or with specific protins. Of course, we admit that although plausible, such a secondary structure for the 3' end of globin mRNA may be totally incorrect, and that proof of this or any other arrangement must await the results of direct physicochemical studies. Whether or not the  $\alpha$  mRNA sequence has the type of secondary structure shown in Fig. 4 is also of great interest, but await further study. Considerable homology does exist, however, between the two mRNA sequences as would be predicted for two such functionally related molecules.

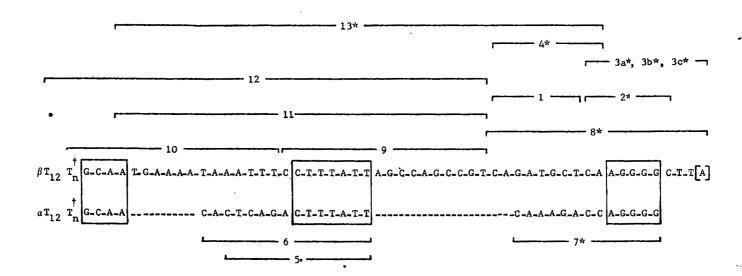

Fig. 3 Summary of sequence data on the oligonucleotides numbered in Fig. 1. The sequence for the cDNA of the  $\beta$  globin mRNA is fully overlapped. The oligonucleotides derived from the cDNA of  $\alpha$  globin mRNA are ordered by homology with the  $\beta$  sequence. Homology between the two sequences is denoted by the boxes.

<sup>\*</sup> The oligonucleotide's 3' end is a result of termination of transcription.  $\uparrow n$  varies depending on the position that the oligo  $dT_{12}$  primer hybrides to poly(A). The square brackets denote a sequence ambiguity.

7

361

The amino ac sequence of rabbit β globin is known<sup>12</sup> so that, using the enetic code, it is possible to partially predict the mRNA sequice corresponding to the carboxyl terminus of the protein by the sequence reported here shows no homology with this reson and it is clear that it is entirely within the untranslated regin. A lower limit of 52 nucleotides for the length of the 3 untranslated region is therefore established. Our recent worl on longer cDNA copies of \( \beta \) globin mRNA has made it posible that the 3' untranslated region is substantially longerthan 52 residues. Molecular weight determinations of mous and rabbit B globin mRNA have suggested that  $\beta$  globi mRNA contains about 200 untranslated nucleotides13,1 (excluding the poly(A)), although it is not known how tese are distributed between the 5' and 3' untranslated regins. Moreover, it can be predicted from the studies on chin termination mutants15 of human a globin mRNA that a least 96 residues are present in the 3' untranslated region. Our results are consistent with these studies.

#### Globin and immunoglobulin mRNA sequences

The sequence of 52 nucleotides adjacent to poly(A) in the mRNA coding for the light chain of an immunoglobulin mRNA has been determined by similar methods to those described here and is described in an accompanying article. In this case, it was demonstrated that DNA polymerase in the presence of manganese, coies the mRNA faithfully. Thus, we have no reason to susject that the sequence reported here has any errors due to nistakes in transcription.

Figure 5 shows a comparison of the β globin and immunoglobulin light clain mRNA sequences. A striking sequence and structural homology exists between these two mRNAs, if the globin mRNA sequence is drawn in the 'b' form of Fig. 4. The homology between the two mRNAs may be considered in two parts, sequence and structure. Both possess the sequences A-A-U-A-A-G and U-U-G-C-poly (A) (enclosed within the boxed area of Fig. 5). These two sequences are also present

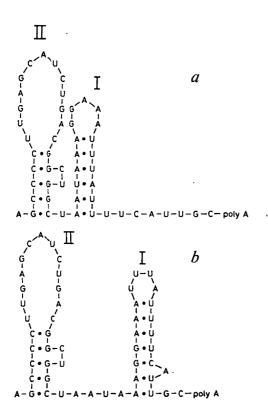

Fig. 4 Two possible conformations for the  $\beta$  globin mRNA sequence drawn in such a way as to maximise base pairing. I and II, hairpin loops whose estimated stability is discussed in the text.

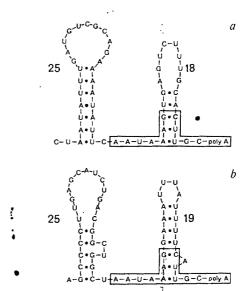

Fig. 5 Comparison of the 3' end of a, mouse immunoglobulin light chain mRNA with that of, b; rabbit  $\beta$  globin mRNA. Sequence in boxes denotes homology between two mRNAs. Number adjacent to each hairpin loop denotes the total number of nucleotides in that loop.

in  $\alpha$  globin mRNA (Fig. 3). A double hairpin-loop structure can be drawn for both  $\beta$  globin and immunoglobulin light chain mRNA (Fig. 5). The loops are identically positioned with respect to each other and are almost the same size in the two mRNAs. The sequence homologies mentioned above are in both cases at the base of the smaller loop and are again identically positioned. Much of the homologous sequence is therefore probably in an accessible unpaired region.

The striking similarity, both in sequence and in secondary structure between globin and immunoglobulin mRNA suggests that this untranslated region of the two molecules has a common function. One part of this sequence, that immediately adjacent to the poly(A) (U-U-G-C) may well be recognised by poly(A) polymerase<sup>17</sup>. This nuclear enzyme is thought to be responsible for the post-transcriptional addition of poly(A) to mRNA precursors<sup>18</sup> (HnRNA). *In vitro* studies have shown however, that this enzyme has no requirement for a specific sequence<sup>18</sup>. This apparent contradiction may result from different specificities *in vitro* and *in vivo*. Whether the rest of the structure is also involved in the recognition of poly(A) polymerase is more speculative, but it is tempting to suggest that the whole boxed area of Fig. 5 may be involved.

Messenger RNA is known to bind specific cytoplasmic proteins<sup>20,21</sup> which may be involved in general functions such as the transport of mRNA from the nucleus to the ribosome or control of the degradation of mRNA. The double hairpin-loop structure reported here could also be the recognition site for such proteins but such suggestions must be regarded as speculative in the absence of direct experimental evidence. Sequence studies on other purified mRNAs will reveal how general and therefore how functionally important are these sequence and structural homologies.

### Early Tertiary hiatuses in the north-eastern Indian Ocean

#### A. C. Pimm

Scripps Institution of Oceanography, La Jolla, California 92037

#### J. G. Sclater

Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

Cores from drill sites in the Indian Ocean have provided evidence of early Oligocene and early Eocene-Palaeocene hiatuses. That allows a determination of the depth of the carbonate compensation level during the Palaeocene. Possible reasons are given for the occurrence of the early Oligocene hiatus, which may be present at all depths and may well be a world wide phenomenon.

ONE of the major discoveries of the Deep Sea Drilling Project (DSDP) has been the frequent, oceanwide occurrence of discontinuities and hiatuses in the sediment record. Some of these are not just local phenomena but must be related to regional oceanic events1-2.

There are two types of hiatus: first, a hiatus in a continuously cored interval—this is indicated by missing palaeontological zones; second, a hiatus in an uncored or undateable interval. In the second case a hiatus is presumed to exist when the depth-age charts (with age bars showing the time range of each zone) unequivocally indicate that the sedimentation rate over a certain interval (the hiatus) is less than one tenth of the rates in the immediately overlying and underlying sediments.

There is a correlation between depth and age of the oceanic crust which holds in all oceans4. Subsidence curves based on this relationship, adjusted for the thickness of sediment between the ooze-clay boundary and volcanic basement<sup>5,6</sup>, can be used to determine the past depth of the carbonate compensation level, and also the depth range throughout which a hiatus occurred. Some hiatuses in the present sedimentary record are related to patterns of deep water flow7,8. Similarly, the ability to relate some of the older hiatuses to changes in deep and shallow water flow patterns will greatly increase the quantitative understanding of oceanic sedimentation.

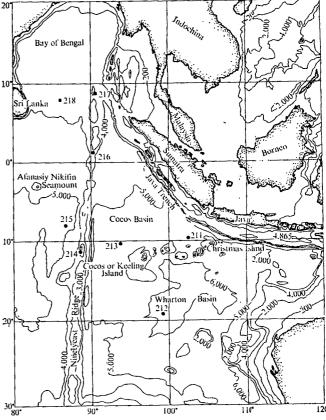

Results from Leg 22

The DSDP Leg 22 drill sites are shown in Fig. 1 and lithologies are summarised in Fig. 2. Cores from the Ninetyeast Ridge (Fig. 1, holes 214, 216, 217) showed calcareous oozes overlying a shallow water basal calcareous sequence. Volcanogenic material was also present at sites 214 and 216. The age of the basal sediment increases northwards. Holes 213 and 215, on

either side of Ninetyeast Ridge, show siliceou ooze passing down into brown clay and finally into calcarects ooze.

At drill sites 213, 214, 215, 216 and 217, hiauses centred on the early Oligocene can be inferred from the recovered cores, and at sites 214, 216 and 217 hiatuses can also beinferred in the early Eocene-Paleocene.

At site 211 two cores taken in a 100-m interval between

Leg 22 sites • plotted on the Russian bithymetric chart of the Indian Ocean (Udintsev, personal communication).

Pliocene and Matrichtian sediments contained small amounts of barren brownlay. At site 212 there was a total of almost 90 m of brown classeparated into several units by redeposited calcareous ooze, he clay must have accumulated over a period of about 80–10 Myr. Therefore, at both of these deep water sites hiatuses canot be inferred from our data (compare with the hiatuses repreted in Fig. 1 of ref. 3) because of the poor

fossil control and because the assumed sedimentation rate for brown clay was close to normal over the entire interval in question.

Cores from sites 213 and 215, on either side of Ninetyeast Ridge, imply a major hiatus in the mid Tertiary. At site 213 about 12 m of unfossiliferous clay separates the Middle Eocene from early Middle Miocene—a time span of about 30 Myr;

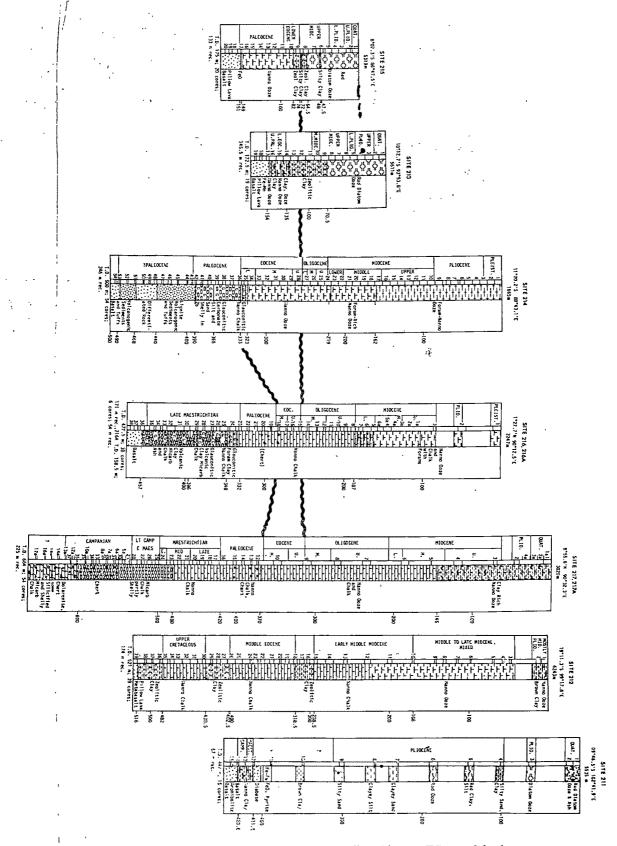

Fig 2 Stratigraphic logs of Leg 22 sites; wavy lines, hiatuses. T.D., total depth.

and at site 215 only 4 m of clay separates early Eocene from late Miocene—a time span of 40 Myr.

At site 214 two cores (20 m) span the entire early Oligocenelate Eocene interval—a period of 10 Myr—so it seems that a small hiatus can be inferred, because the accumulation rate is less than one tenth of the typical rate for pelagic calcareous ooze. At site 216 the nannofossil evidence indicates that the early Oligocene interval is only represented by about 2 m of sediment. One core from site 217 shows a hiatus from the late Eocene to the mid Oligocene.

In the core from site 214, between 336.5 and 334.5 m there is a hiatus of at least 4 Myr between Foraminifera zone P4 (Palaeocene-56 Myr) and zone P7 (early Eocene-52 Myr). At site 216 no early Eocene Foraminifera were recovered, although possible early Eocene nannoplankton were observed in the core catcher sample of one core. The upper portion of that core was Middle Eocene and the core immediately below was Palaeocene. Therefore, at best only a very small part of the early Eocene is preserved. At site 217 the early Eocene and topmost Palaeocene are represented by a very condensed sequence, unless part of the section is missing: Middle Eocene nannoplankton (Chiasmolithus grandis Zone) are separated from Palaeocene (Discoaster multiradiatus Zone) sediments by a 20m interval only.

#### Nature of hiatuses

The major hiatuses in the cores from sites 213 and 215, which are situated in the deep ocean on either side of the Ninetyeast Ridge, are centred close to 35 Myr BP, and the cores from sites 214, 216 and 217, on the Ridge, also revealed smaller hiatuses very close to 35 Myr BP. The cores from the latter sites also indicated small hiatuses between 50-56 Myr BP.

Using the palaeontological dates assigned to the major lithological units (Fig. 2) we plotted the sedimentary record of each site on to oceanic subsidence curves (Fig. 3). For the oceanic sites we computed the expected depth of the site from the empirical curve for normal oceanic crust4. We assumed that the sites on Ninetyeast Ridge were formed close to sea level, had a shallow water history, and subsided at the same rate as the Indian plate, to which they were attached10. We also adjusted the curves for sites 214 and 217 by eye, to give the existing oceanic depth (Fig. 3). From these subsidence curves we have assigned palaeodepths to various features of the sedimentary record.

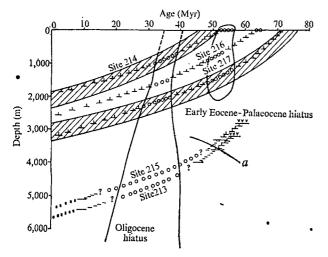

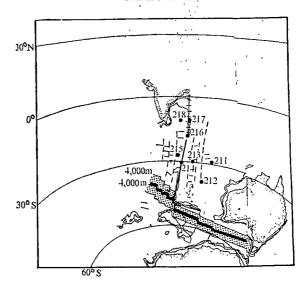

Fig. 3 Geological history of the sites, with hiatuses superimposed on oceanic subsidence curves. a, Carbonate compensation level; 000, hiatuses; careous sediments; SSS, siliceous ooze; ———, cl -, clay; basalt.

The region of the ocean floor postulated i be shallower than 4,000 m from the depth-age relationship superimposed upon the 32 Myr BP reconstruction of the relatie positions of Antarctica, Australia, and India 10. Assuming an oening time of 55 Myr BP the depth of the crust between Austraa and Antarctica would fall below 4,000 m for the first timespproximately 40 Myr BP.

Sites 213 and 215 record a change from carbnate to brown clay deposition at 3,600 and 3,300 m respectivey (Fig. 3). This effectively gives the approximate palaeodepth o the Palaeocene level of carbonate compensation in the eastern Indian Ocean.

The major hiatus at sites 213 and 215 occursit palaeodepths of 4,000-5,0000 m. Sites 214, 216 and 217 eacl show two hiatuses. The younger (Oligocene) occurs throughout depths between 1,000 and 2,500 m, and the older (earlyEocene) occurs. only at depths shallower than 2,000 m.

It therefore seems that the Oligocene liatus probably affected, to varying degrees, all of the site postions, irrespective of depth, and also that the Palaeocere-early Eocene hiatus was restricted to depths shallower than 1,500 m.

Evidence from DSDP legs in the Pacific and Atlantic indicates that the Oligocene hiatus is probably worldwide. We speculate that it may have developed in response to a worldwide readjustment of oceanic circulation. Such a realjustment could be a result of two major events which occurred during the Oligocene: during this Period there was interse glaciation in Antarctica<sup>11</sup>, and for the first time an effective deep water, circumpolar circulation system could have been established between Australia and Antarctica. Antarctica separated from Australia roughly 55 Myr BP (ref. 12). The subsidence curve data from the oceanic crust just north of Antarctica indicates that this region would have subsided from 2,700 n at the time of separation to more than 4,000 m by 40 Myr P. Such a depth would allow deep bottom water from further to the west to pass around the north of Antarctica, possibly establishing the Antarctic bottom water circumpolar current (Fig. 4).

We further suggest that the Palaeocene-early Eocene hiatus, which affects only shallow depths on the Ninetyeast Ridge, may be an event related solely to local tectonism.

### Optical variability of PKS0048-097

Hoskins et al. have identified the Parkes radio source 0048-097 with a neutral tellar object of 17 mag, and Carswell et al.2 have shown that, it common with the BL Lacertae class of quasistellar object BL Lacertids) it has a featureless optical spectrum, that it is a rapid radio variable at high frequencies3-6 and that it has a ralio spectrum similar to BL Lacertae<sup>3</sup>. (The name 'Lacertid' has been suggested' for this class, but this invites confusion withmeteor showers.) To complete the identification of PKS0048-017, we have investigated two further characteristics of the BL'Lacertids: the rapidity of the optical variability; and the total range of optical variability and its correlation with the decimetric pectral index8.

Thirty-three blue photographic plates from the Harvard archives, taker between 1921 and 1955 (27 between 1948 and 1955); were neasured with a Cuffey Iris Astrophotometer. Relative magnitudes were derived from a reference sequence around the object, which was obtained by a transfer from Mount Wilson Selected Area 117 (see ref. 8). The total amplitude,  $\Delta m_{pg}$  was found to be 2.7  $\pm$  0.3 mag. The available plates cover only a linited time and so this amplitude should be taken as a lower limit. In addition, on two occasions in 1948 the object exhibited rapid increases in brightness of about 1.4 mag in 55 d and about 0.9 mag in 30 d. Moreover, PKS0048-097 fits an empirical relationship, which exists for BL Lacertids<sup>8,9</sup>, between  $\Delta m_{pg}$  and the decimetric spectral index  $\alpha$ . From the measurements of flux density, S, of Shimmins et al.10 at frequencies, v, of 408 and 2,650 MHz, the value of  $\alpha$  (=  $d\log S/d\log v$ ) was found to be 0.33. This value of  $\alpha$  should only be considered as representative because of the known radio variability of the source3-6.

It is significant that a value of about 1.5 mag seems to be the lower limit on the total amplitude,  $\Delta m_{pg}$  for BL Lacertids with a substantial optical record9. This empirical result includes PKS0537-441, for which  $\Delta m_{yy}$  is at least 4.9 mag (ref. 11), as well as B20912+29 (ref. 12 and J. T. Pollock, unpublished). We conclude that radio sources with  $\Delta m_{pg} \gtrsim 1.5$  mag should be considered as prime candidates for the BL Lacertae class, and that the use of archival photometric records may be an efficient means of identifying new BL Lacertids.

Concerning the nature of PKS0048-097 and the BL Lacertids in general, Oke and Gunn<sup>13</sup> have shown that the extended object around the quasistellar source BL Lacertae has the spectrophotometric properties of an ordinary giant elliptical galaxy, with a redshift of 0.07. Similar results have been obtained by Wlerick et al.14. Furthermore, if we make the reasonable assumption that the K correction for this galaxy is about 0.1 mag, then it can be shown with the help of the Oke and Gunn data that the BL Lacertae galaxy fits the Hubble diagram of Sandage15 for radio and N galaxies within the scatter of the points. BL Lacertae is thus associated with an E galaxy that has an intrinsically high luminosity, but is otherwise a normal redshifted object, and it is reasonable to induce that all BL Lacertids have similar properties. The suggestion that these objects are blueshifted16 is thus unlikely to be

correct and therefore a major requirement of the local hypothesis for quasars (that they are ejecta from the Milky Way and/or nearby galaxies) apparently cannot be satisfied by the BL Lacertids. It follows that the problem still exists of accounting for the large power radiated by the BL Lacertids and other quasistellar objects at their cosmological distances.

To explain the energy requirements Hjellming<sup>17</sup> has suggested that quasistellar objects are singular 'white holes' which are multiply connected to black holes in our own or some other universe. According to Burbidge18, the basic concept of white holes originated in the writing of Sir James Jeans in 1929, and has occasionally been revived by Ambartsumian, Hoyle and others. Unfortunately, no theoretical predictions exist for comparisons with observations, and indeed, according to Hjellming (private communication) the hypothesis is highly speculative. Nevertheless, it is well known that most galaxies and many ellipticals have bright semistellar nuclei, and on the basis of morphology it would seem more reasonable to regard the phenomenon of quasistellar objects as an extreme case of bright galactic cores, with which are associated singularities caused by gravitational collapse, rather than white holes.

We thank Harvard College Observatory for their hospitality.

#### Solar models with rotating cores

It is possible to achieve low solar neutrino fluxes with solar models with rapidly rotating cores<sup>1-3</sup>. But to achieve a flux consistent with the 1 SNU (1 SNU =  $10^{-36}$  neutrino capture per (target atom s-1) upper limit of Davis4, the rotation must be so rapid that the approximate treatment of rotation used is of doubtful validity. Further it is difficult to obtain a result simultaneously giving a flux less than 1 SNU and a solar oblateness consistent with observation<sup>5</sup>. Sakurai<sup>6</sup> has shown that it is possible for Eddington-Sweet circulation to transfer angular momentum both inwards and outwards in solar models with rotating cores on a time scale much less than the solar lifetime. Thus as the Sun evolves, its rotating core gets smaller while its outer part spins up. This suggestion has les us to investigate the possibility that this spin-up might lead to the onset of some transient phenomenon, such as the sudden beginning of thermal convection. Under special circumstances, a transient state can lead to temporarily depressed fleutrino fluxes7-10. It was hoped that the transient phase induced by spin-up, coupled with an already depressed flux due to the rotating core would lead to a flux of less than 1 SNU while requiring less extreme transients or rotation than is necessary when these effects are applied separately. In addition, a mechanism for the transient would be provided. Unfortunately this hope has not been realised and additional problems with rotating solar models have been discovered.

As in earlier work, we take rotation into account by multiplying the pressure gradient by a factor containing the average centrifugal force,

$$\frac{dP}{dM} = -\frac{GM(r)}{4\pi r^2}F, \quad F = 1 - \frac{2r^3\Omega^2}{3GM(r)}$$

The radiative gradient, as calculated from the luminosity and used in testing for thermal convection, must be divided by F. According to Sakurai's model, the radiative core of the Sun is initially rotating with a constant angular velocity. Because of induced circulation currents, angular momentum is transported from the surface towards the core. Additionally the outer regions can lose angular momentum to the solar wind. To maximise the final rotation rate, and because the angular momentum transferred to the solar wind depends on the surface rotation rate, we have neglected the surface loss of angular momentum. The Sun as a whole therefore conserves its angular momentum and as the surface layers rotate more slowly, the inner region must rotate more rapidly. The distribution of angular velocity in the transition region between the slowly rotating surface region and the uniformly rotating core region is governed by the condition that it must remain stable against shear flow turbulence. The onset of shear flow turbulence in a stratified medium occurs when the Richardson number

$$Ri = -g \mid (\partial \ln \rho / \partial r) - (\partial \ln \rho / \partial r)_{ad} \mid (\partial u / \partial r)^{-2}$$

is less than some critical value. In this formula g is the acceleration of gravity and  $\partial u/\partial r$  is the velocity gradient associated with the differential rotation. We recognise that other instabilities may be associated with the differential rotation, but feel that shear flow turbulence almost certainly will transport angular momentum efficiently even on a short time scale. Thus we have set an upper limit on the velocity gradient by requiring  $Ri \ge 1/4$ . The width of the rapidly rotating shell is then determined by the condition that this shell contains the angular momentum lost by the outer envelope. Since this shell contains not only its initial angular momentum, but also the angular momentum lost by the envelope, it must rotate more rapidly than the core. We should therefore apply the Richardson condition on both sides of the shell. But in order to maintain a relatively simple computing algorithm and test

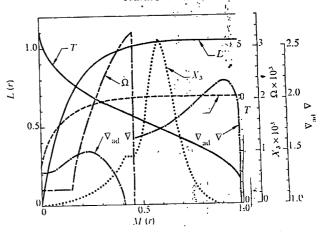

Fig. 1 Structure of sequence-B at an age of  $4.7 \times 1^9$  yr. Quantities shown are temperature T ( $10^6$  K), hydrogen has fraction  $X_3$  rotation rate  $\Omega$  (rad s<sup>-1</sup>), <sup>3</sup>He mass fraction  $X_3$ , ratio of adiabatic gradient to actual gradient in the star  $V_{\rm d}/V_{\rm t}$ , and the luminosity L ( $L_{\odot}$ ). The convective region is the small zone where  $V_{\rm ad}/V = 1$ . X = 0.69; F = 0.02;  $\Omega_0 = 3.10^{-4}$ ; Ri = 0.25;  $\varepsilon = 6.4 \times 10^{-3}$ ;  $\Sigma \Gamma \varphi = 13.2$ .

the importance of satisfying the Richardson condition, we have required the velocity gradient to obey his condition only on the inner side of the shell. On the over side of the shell we allowed the rotation rate to jump disontinuously to zero. Our procedure then was to choose some inform initial rotation rate  $\Omega$ . At later times we assume if the angular momentum exterior to a mass  $M\Omega$  has been transferred to the rapidly rotating shell. We assume that  $M\Omega$  dereases linearly with time. Our procedure produces a high pear rotation rate and enhances the possibility of inducing a transent. Normally the models were mixed only in those regions whee the criterion for thermal convection was satisfied althoughit would have been more realistic to mix in the region of differential rotation also. The difference between these two cases is small.

The oblateness in each model was calculted following Goldreich and Schubert11. Their equation (14)was integrated from the centre outwards and surface inwards and integrations performed until the oblateness and its derivative were continuous at some matching point. We find oilateness more than an order of magnitude larger than that found by Demarque et al.1 (DMS). We have obtained similar results from programs written independently by each author and have identified the source of the discrepancy. In the nodels studied there is a discontinuity in  $\Omega$  at the edge of the rotating core. The equation to be solved contains a term  $d\Omega^2/dr$  and thus must satisfy a jump condition at  $r_{\Omega} = r(M_{\Omega})$ . This is easily accomplished by letting  $d\Omega^2/dr = -\Omega_c^2 \delta(r-r\Omega)$  near the core edge, where  $\Omega_{c}$  is the angular velocity at the core edge and  $\delta(r-r_{\Omega})$  is the Dirac delta function. In our sequence B described below, which is equivalent to DMS sequence C4, we find  $\epsilon = 2.8 \times 10^{-3}$  and they find  $\epsilon = 1.59 \times 10^{-4}.$  If we neglect the jump condition, we find  $\epsilon = 1.58 \times 10^{-4}$ . Thus it seems that DMS have not properly dealt with the core boundary. We note that the large  $\epsilon$  would remain if  $\Omega$  at the core boundary dropped rapidly, but not discontinuously, to zero. As a further check, we made a crude approximation of the model shown in Goldreich and Schubert's Fig. 2 and find an  $\epsilon$  consistent with theirs.

We have computed two sequences (designated A and B) which are essentially the same as the DMS sequences C2 and C4. The rotating core was handled in the same manner as DMR rather than as described above except that mixing was allowed when the modified criterion for convection was satisfied. Much of the core was convective throughout the sequence. Some of our results for this case are shown in the first two columns of Table 1. The agreement with DMS is remarkable in most respects, even to the agreement of the fluxes from the individual reactions in sequence E. There are, how-

ever, crucial deferences between our results and DMS. It is likely that the angular momentum lost from the core would have been transferred bymass-motion, possibly Eddington-Sweet circulation. Ulrich¹² has pinted out that this would play havoc with the light element abundances at the solar surface. Here we have not even made this assumption and mix only when instability for thermal convection exits. But during the very early stages, the convection zone is deep enough to enhance the surface ³He from 0 to  $1.5 \times 10^{-4}$  by mass. This is above the upper limit observed by Hall¹³. It will be exceedingly, difficult to produce rotating models which do not have such produms with ³He or the even more sensitive Li and Be.

As noted above, we find a much larger oblateness,  $\varepsilon = 4.6 \times 10^{-4}$  and  $2.8 \times 10^{-3}$  compared to their  $\varepsilon = 2 \times 10^{-5}$  and  $1.6 \times 10^{-4}$ . Our results are in strong disagreement with the observed value<sup>5</sup> of  $\varepsilon = 5 \times 10^{-5}$ , which can be taken at least as an upper limit.

There are several possibilities for inducing a transient phase with a core that is spinning up. First, we suppose that the outer part of the rotating core arrives at some part of the <sup>3</sup>He peak after 4.7×10° yr of evolution. This could well cause the simultaneous onset of thermal convection. Because of the stored energy in the <sup>3</sup>He and the modified radiative gradient inside the rotating core, it is conceivable that the convective region might grow. But our calculations show that mixing

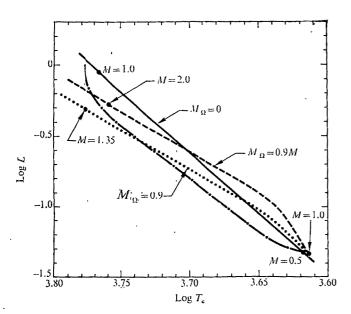

Fig. 2 H-R Diagram for main sequence models for the composition X=0.712. The solid line is the non-rotating main sequence, the long dashed line has  $M_{\Omega}=0.9M_{\odot}$ , the short dashed line has  $M_{\Omega}=0.9M$ ; in the rotating cores F=0.50. Reference marks  $(M_{\odot})^{\dagger}$  are shown on each sequence. The evolutionary track for model B is also shown (dot-dash line).

never occurs except for rotation rates almost as large as those used by DMS.

The results for one model (designated C) which developed a convective region are shown in the second column of Table 1. The initial rotation rate was  $3\times 10^{-4}\,\mathrm{s}^{-1}$ . While evolving for  $4.7\times 10^9$  yr the rotating core was reduced from  $0.98M_\odot$  to  $0.46M_\odot$ . At this point, a small convective region developed. Figure 1 shows the structure at this time. Comparison of our curve for  $\Omega$  and Sakurai's Fig. 2 emphasises the extremes we must have to get any effect. The convective region is on the inner slope of the <sup>3</sup>He peak. Further evolution with small time steps and no further reduction in the rotating core size show that the convective region does not grow, but rather shrinks in size. The curve for the ratio of the adiabatic gradient to actual gradient in the star,  $\Lambda_{\rm ad}/\Delta$  in Fig. 1, shows that the central core is extremely stable.

There are further problems with this model. To achieve the proper luminosity, X had to be reduced to 0.69 initially. Thus the neutrino flux ends up at 13.2 SNU which is more than double our standard Sun. Further, the oblateness of this model is more than 100 times larger than Dicke's value. Certainly any model which has any substantial rotational modification in the <sup>3</sup>He peak will suffer similar oblateness problems.

The results for a similar model in which the composition was mixed in the differentially rotating region is shown in column 4 of Table 1. It differs little from the previous model.

One additional possibility remains: if the differentially rotating region reaches into the central region of high nuclear burning, the addition of <sup>3</sup>He from the outer part of the model might lead to further mixing driven by nuclear burning. Such a sequence (designated E) is shown in column 5 of Table 1. Mixing has been allowed in the differentially rotating region and the inner edge of this region is at  $0.073M_{\odot}$ . The mixed region has been extended over a larger mass than sequence D by making the Richardson number larger. The region unstable to thermal convection extends from 0.421 to  $0.450M_{\odot}$  and again has no inclination to grow. The oblateness is still burge

So it seems that the only possibility for the spin-up to induce a neutrino-eliminating transient would be for the rate of spin-up to be extremely fast.  $M_{\Omega}$  would have to be reduced from say  $0.6M_{\odot}$  to  $0.1M_{\odot}$  in a time comparable to the <sup>3</sup>He lifetime at the centre ( $\sim 10^5$  yr). This rate of spin-up seems implausibly high.

The models proposed by DMS seem to be ruled out as solutions to the solar neutrino problem. (Roxburgh does not describe his models in sufficient detail for us to check, although they seem very similar to those reported by DSM.) Their oblateness is much greater than the observed value. Their <sup>3</sup>He at the surface is above the observed upper limit. Finally a problem which will afflict all such models is demonstrated

in Fig. 2. A non-rotating main sequence is shown along with ones with two different values of  $M_{\Omega}$  and the evolutionary tracks for sequence B. In a cluster of stars similar to the Sun one might expect to find stars scattered throughout the region between the non-rotating main sequence and one of the rotating ones. A typical spread at a given  $T_c$  is 0.2 to 0.3 in  $\log L$ . This spread of 0.75 mag is not observed in Praesape<sup>14</sup>, for instance.

We thank Professor William A. Fowler for suggesting this approach. The computations were supported by a University of Virginia Computing Grant. This research was also supported in part by the National Science Foundation.

### Oblateness of solar models with rotating cores

Rood and Ulrich1 have discussed the oblateness of solar models with a rotating core. They find a larger oblateness for the same model than we did2. We have looked again into the oblateness calculation and now believe that the correct solution of the equations of Goldreich and Schubert3 gives an oblateness for the final model of our2 sequence C4 in agreement with the value derived by Rood and Ulrich. We also agree with Rood and Ulrich's explanation for the discrepancy.

#### Geomagnetism and the tropospheric circulation

In a recent article in Nature1, King draws attition to certain similarities between the atmospheric flow utern in midtroposphere and the Earth's magnetic field. He stulates "some unknown magnetic-field dependent mechanism which exerts a control on the tropospheric circulation and acciated atmospheric pressure field. The evidence on which hoases this idea consists of the similarity between the distribution of the height of the 500-mbar pressure surface in the atmosphre and that of the geomagnetic field strength, particularly in latude 60°. He supports this with some indication that the features of the 500mbar surface have moved westwards in parallel wh the features of the geomagnetic field.

The purpose of this communication is to poir out that it is unnecessary, and probably misleading, to postulte any causal relationship between the geomagnetic field andthe 500-mbar contours, because the main features of the mar of 500-mbar contours can be explained by direct calculation rom physical and dynamical principles without consideratio of magnetic effects. Moreover any westward movements of theeatures of the

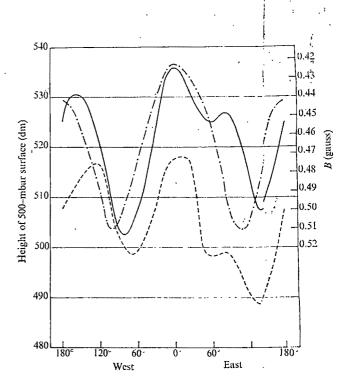

Fig. 1 Longitudinal variation of 500-mbar heightand magnetic field strength along latitude 60°N in January. — Observed 500mbar height from ref. 6; --- dynamically computed 500-mbar height; ---- magnetic field strength from Fig. 2 of ref. 1.

500-mbar height field appear to be merely the result of temporary fluctuations, and therefore unlikely to belinked with the westward motion of geomagnetic features which has continued over a century or more.

In recent years a great deal of effort has been devoted to the numerical solution of the equations of motion of the atmosphere, together with the thermodynamic equations, equations for radiative transfer and the mathematical representation of the other physical processes in the atmosphere. Given the external heat sources—the solar radiation—and appropriate thermal and mechanical boundary conditions at the Earth's surface, the aim has been to calculate the global atmospheric circulation and such related features as the distribution of temperature and pressure. The atmospheric circulation is far from being steady,

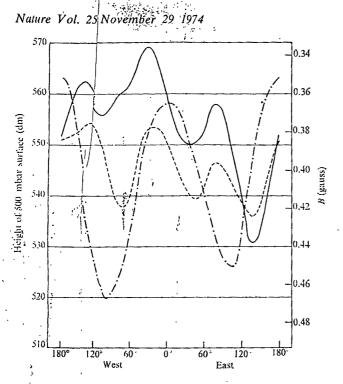

Fig. 2 Lonitudinal variation of 500-mbar height and magnetic field strengtl along latitude 40°N in January. (Explanation as Fig. 1.)

and the shor period disturbances—the depressions and anticyclones—play an essential role in maintaining the average circulation. The numerical calculations reproduce this feature. Starting from an arbitrary initial state, and integrating with respect to time, they reproduce the irregularly fluctuating character of the atmosphere. The mean seasonal circulation can be obtained by averaging over a period of some 30 d or more. A considerable degree of success has been obtained in such calcu-

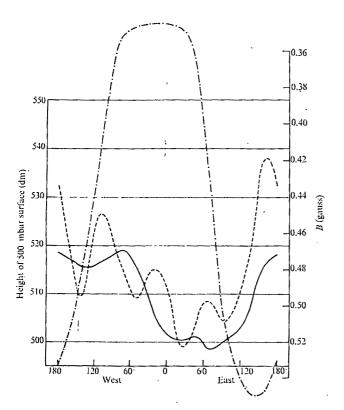

Fig. 3 Longitudinal variation of 500-mbar height and magnetic field strength: along latitude 60°S in July. (Explanation as Fig. 1 except that observed 500-mbar height is taken from ref. 9.)

lations and full reports have been published by several independent research groups<sup>2-4</sup>.

To illustrate this, I have taken the calculated profile of 500-mbar height around latitude 60°N from an integration performed during the course of one such numerical experiment with the model of Gilchrist, Corby and Newson<sup>5</sup> and plotted it in Fig. 1 along with the observed January profile as mapped by Heastie and Stephenson<sup>6</sup>. All the main features are fairly well reproduced although there are some small mislocations and incorrect intensities of the troughs and ridges. (The geomagnetic field strength B at 400 km is reproduced from ref. 1 for comparison.) It is noteworthy that the dynamical calculations reproduce the weak ridge at 80°E whereas there is no corresponding feature in the geomagnetic field. It is also noteworthy that the 500-mbar profile around latitude 40°N is also reproduced fairly well by the calculations (Fig. 2) although here

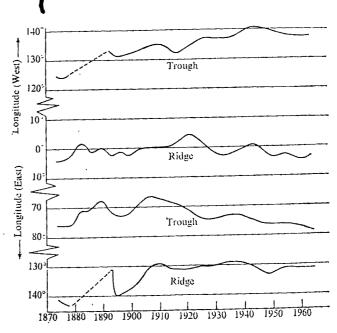

Fig. 4 Longitude of the main 500-mbar troughs and ridges at . 500-mbar as a function of time based on 10-yr running means (December-February).

the dominant wave number is three and not two as in the geomagnetic field.

Figure 3 shows similar profiles for latitude 60°S, also in winter. Here the observations are probably inadequate to define the observed field with any reliability but the agreement between calculated and observed distribution is such as to suggest that a geomagnetic effect need not be invoked to explain the main features of the profile and in particular the dominant wave number one.

King<sup>1</sup> uses a comparison of two sets of climatological charts as evidence for the westward movement of the features of the 500-mbar height field between the 1930s and 1950. The data available for the preparation of the earlier charts does not really warrant such a comparison, indeed the second set were prepared as a replacement of the earlier set when more data became available, and I am sure that the authors of the earlier charts would attribute the differences to lack of data rather than to any real change. More recently, in the course of research in long-range forecasting, a set of monthly charts of the 500-mbar heights for each year since 1874 has been built up in the Meteorological Office. In the earlier periods, when data for the

500-mbar level were lacking, these charts are obtained by a correlation procedure based on the surface pressure chart for which adequate observations are available. Figure 4 shows the changes in the longitude of the main 500-mbar troughs and ridges as a function of time. This diagram is based on 10-yr running means for the winter period (December-February). Although there is some confirmation of a westward displacement of these features (except the East Asiatic trough) in the period leading up to 1950, the pattern is one of irregular movements during the whole period, without much overall displacement. On the other hand the movement of the geomagnetic features has been believed to be westwards (albeit irregularly) at least since the early nineteenth century<sup>7,8</sup>. It does not, therefore, seem reasonable to seek an association between the erratic movements of these atmospheric features and the more or less steady progression of the geomagnetic features.

DR KING REPLIES—It is widely believed that long term changes in the circulation of the lower atmosphere will be accompanied by climatic variations. The causes of these changes have not yet been established and at the present time, therefore, they are not predictable. I and other workers (see ref. 1) have suggested that the Earth's magnetic field may influence, through some unknown mechanism, the behaviour of the lower atmosphere at high latitudes in winter. Examples showing the type of evidence on which this suggestion is based are shown in Fig. 1; further evidence will be published elsewhere. I pointed out that such magnetometeorological evidence "cannot be construed as proof that the Earth's magnetic field and the average tropospheric pressure patterns are related, but it does suggest that more work on this problem should be undertaken.'

Sawyer<sup>2</sup> claims that "it is unnecessary, and probably misleading, to postulate any causal relationship between the geomagnetic field and the 500-mbar contours . . . " Several major objections can be made to this claim:

(1) It is based on the belief that the Meteorological Office model yields theoretical results in such good agreement with observations that it is unnecessary to postulate the existence of hitherto unconsidered relationships which might exist between the lower atmosphere and, for example, the geomagnetic field. Not all atmospheric modellers, however, would accept that current models yield such satisfactory results. Smagorinsky3, for example, says in the introduction to a GARP volume describing the 19 meteorological models currently known to exist: "All present models are sufficiently different from the real atmosphere so that, when real data are used with any one of them ... the conclusions are highly model-dependent." He continues: "The traumatic response of a model to alien data, for example conditioned by another model or, even worse, by the atmosphere itself, may often take the form of outright rejection of the

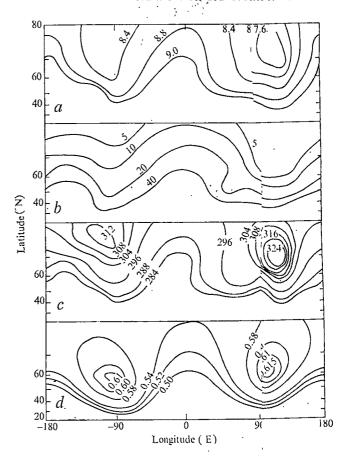

Fig. 1 a, b, c, Northern Hemisphere average rado refractivity maps, compiled by Bean et al. 10 from radiosade data for November 1958-62. a, Radio refractivity 'dry tern' tropospheric scale height (km); b, mean sealevel radio refractivity, 'wet term'; c, mean sealevel radio refractivity, 'dry term'. Tie maps effectively illustrate the spatial variations of, respectivey, the average tropospheric temperature, sealevel humidity and sealevel air density. d, Variation of total magnetic intensity (c.g.s. units) at the Earth's surface11.

transplant attempt." These statements indicate that even the best of the available models do not produce results in satisfactory agreement with the real atmosphere. Manab: and Terpstra4, after a major study carried out using the general circulation model developed at the NOAA Geophysical Huid Dynamics Laboratory, concluded that as far as the Northern Hemisphere is concerned: "The agreement between the distributions of geopotential height of the 500-mbar level surface in the mountain-model atmosphere and that in the actual atmosphere is particularly poor in higher latitudes." These are the latitudes for which I suggested that the geomagnetic field may exert a controlling influence on the tropospheric circulation1. As far as the Southern Hemisphere is concerned. Manabe and Terpstra4 reported: "The simulation of the flow field has much to be desired" and "The agreement between the computed and observed (pressure maps) is poor". The results of the calculations were judged to be "not very realistic" because "the intense surface westerlies in the middle latitudes of the Southern Hemisphere are almost missing" in the results obtained using the mountain model.

Some measure of the disagreement can be obtained by noting that the correlation coefficient between the observed and calculated 500-mbar height values at 60°N in January (from Fig. 1 of ref. 2) is only 0.69. The correlation coefficient between the observed 500-mbar data (shifted 25° westwards in order to allow for the height-dependent phase shift of the pressure variations) and the total intensity of the Earth's magnetic field at the Earth's surface is, however, -0.90, while that between

the January 50(mbar heights (phase-shifted) given by Palmen and Newton<sup>5</sup> an the intensity of the magnetic field for 60°N is -0.963. Such |gh correlation coefficients are very unusual and, although tey do not prove anything, their implications should not be dmissed lightly. The modelling work referred to above clearly sggests that the present understanding of the atmosphere emodied in the models is inadequate and that further interdisiplinary research is needed to discover what has been omitted from the models.

(2) Sawyer suggests that the numerical work which he refers to is based only on physical and dynamical principles and that it does not, theifore, take into account magnetic effects. This is not necessaril true; the results were obtained using the model of Gilchrist eal.6 which incorporates, as a necessary boundary condition, vales of the observed sea surface temperature which were bld constant throughout the calculations. The temperature rap used by Gilchrist et al. is such that the 6° C isotherm movs 21° towards the north (from 45°N to 66°N) while crossing the Atlantic from America to Europe and 18° northwards wile crossing the Pacific from Asia to America. It is obviously not possible to use the results of calculations which incorporate such boundary conditions to decide whether the Earth's mgnetic field or any other external phenomenon influences the circulation of the atmosphere.

(3) Sawyer clams that the main features of the 500-mbar maps are explained by numerical modelling; one feature of the maps which numerical work clearly cannot yet explain, however, is that they charge on a climatic time scale. Present thinking on the usefulness of numerical modelling in climatic studies is contained in ef. 7. This report, prepared for a session of the Joint Organisng Committee for GARP, says: "It is evident that detailed mathematical simulation of the atmosphere's three-dimensional behaviour cannot be the sole avenue to the study of long period variations of climate (for example, a period of the order of a decade or longer) and that the structure of the current general circulation models is unsuitable for that purpose."

McIntosh and Thom8 have summarised the current usefulness of numerical studies for climatic purposes as follows: "The synoptic and analogue methods of 30-day forecasting do not appear capable of being developed further to any significant extent. It is scarcely an exaggeration to say that in all other respects the meteorologist has, at present, nothing positive to contribute concerning future long range weather prospects. This situation is very unlikely to change until numerical studies of the general circulation are much further advanced than now."

These two quotations draw attention to the need for more knowledge about the processes which will alter the circulation of the atmosphere. One way of finding whether the magnetic field and the weather are related is to undertake, as I suggested1, "further comparisons of meteorological data from widely spaced epochs for which reliable maps of magnetic field strength are also available". Such work will require reasonably accurate magnetic information because the movement of features of the magnetic field pattern are by no means uniform. The manner in which the pattern changes is in fact extremely complex9 and Sawyer's representation of the motions of the geomagnetic anomalies as a "more or less steady progression of geomagnetic features" which are unlikely to be associated with the observed irregular secular movements of atmospheric features is unjustified.

#### Initiation of the proto circum-Antarctic current

THE planktonic foraminiferal species Guembelitria stavensis Bandy (Fig. 1) lived in the austral gulf sea between Australia and Antarctica during the Oligocene, and with the final separation of the two continents at the eastern hinge of the South Tasman Rise, it spread out eastwards into the south-western Pacific. The palaeogeographical distribution and the very short stratigraphic range of G. stavensis in the south-western Pacific provides the first palaeontological evidence of the initiation of the proto circum-Antarctic current in the lower part of the Upper Oligocene.

It has been suggested that the circum-Antarctic current first became operative during either the late Oligocene1 about 30 Myr BP, the Middle Oligocene<sup>2,3</sup>, or the Lower Oligocene<sup>4</sup>. The first two suggestions were based apparently on interpretations of a late Palaeogene regional unconformity in the Tasman and Coral seas and the third was based on an interpretation of Oligocene planktonic Foraminifera from New Zealand.

Fig. 1 Guembelitria stavensis Bandy, × 560; site 276 DSDP Leg 29 (latitude 50° 48.11'S; longitude 176 48.40'E).

<sup>&</sup>lt;sup>3</sup> Smagorinsky, J., Modelling for the first GARP global experiment, World Meteorological Organisation GARP Publications Series No. 14 (Geneva, 1974).

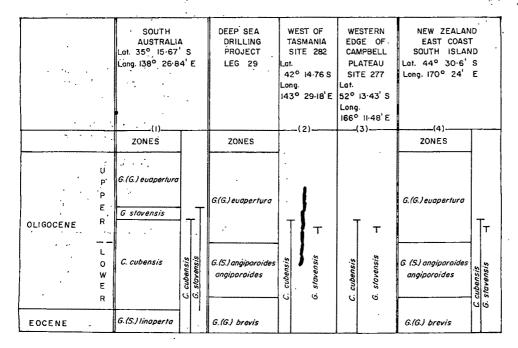

Fig. 2 Stratigraph records of G. stavensis in SouthAustralia, two sites of DSDP Legland one from New Zeand.

The palaeontological dating of the unconformity is basic to the original hypothesis. According to Kennett et al<sup>1</sup>. "The unconformity is centred approximately in the Globigerina angiporoides and Globigerina brevis foraminiferal zones<sup>9</sup> but frequently includes the Globigerina linaperta to Globigerina euapertura zones<sup>9</sup>; or the Isthmolithus recurvus to Reticulofenestra placomorpha zones<sup>10</sup> (late Eocene to Middle Oligocene)." But calcareous nannofossil I. recurvus—R. placomorpha zones have been correlated with the G. (S.) linaperta to G. (S.) angiporoides angiporoides zones in New Zealand<sup>5</sup>, that is the nannofossil zones are older than the G. (G.) euapertura zone and the erosion which formed the unconformity must also be older than that zone.

The stratigraphic and palaeogeographic distribution of *Guembelitria stavensis* which was originally described from the Middle Eocene of Alabama seems to fix the stratigraphic position of the initiation of the proto circum-Antarctic current.

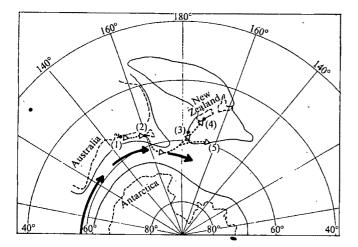

Fig. 3 Tentative migration route of G. stavensis (heavily dashed line) after the initiation of the proto circum-Antarctic current during the Upper Oligocene lowest G. (G.) evapertura zone. The shapes of continental areas (solid lines) are based approximately on the present 4,000 m bathymetric contour<sup>10</sup> (dashed lines show present continental boundaries). Details of present-day localities (1)—(4) are given in Fig. 2. Locality (5) is at latitude 50° 48.11'S; longitude 176° 48.40'E, DSDP Leg 29, site 276. Heavy arrows, proto circum-Antarctic current.

Guembelitria stavensis lived in the southern arts of South Australia during Lower to Upper Oligocene Giloguembelina cubensis – G. stavensis zones times<sup>6,7</sup> and becam extinct in the equivalent of the lowermost G. (G.) euapertura one (Fig. 2). It lived slightly longer there than in areas to theeast, however. Before it became extinct, G. stavensis migrated estwards and is recorded at this stratigraphic level west of Tasmaia at the Deep Sea Drilling Project (DSDP) Leg 29, site 282 Figs 2 and 3).

With the establishment of open sea condition following the separation of Tasmania and its southern continental extension from Antarctica, G. stavensis apparently spreal rapidly eastwards. It is recorded for only a short interval inthe lowest part of the G. (G.) evapertura zone on the western edge of the Campbell Plateau at DSDP site 277 (Figs 2 and 3. Guembelitria stavensis has also been encountered at DSDP site 276 on the eastern edge of the Campbell Plateau (latitule 50° 48.11'S; longitude 176° 48.40'E) and was obtained from a bit-sample presumed to be from the same stratigraphic levil in the G. (G.) evapertura zone. G. stavensis has also been recorded at the same stratigraphic level on the eastern coast of South Island, New Zealand (Figs 2 and 3) but it has not been recorded either north of this locality in the New Zealand Oligecene, or in the Tasman Sea sediments. A southward migration is therefore

I postulate that the migration of G. stavensis eastwards from the region of South Australia into the South Tasman Sea and south-western Pacific was permitted by the initiation of the proto circum-Antarctic current. The relatively short stratigraphic range of G. stavensis at sites east of South Australia appeared and became extinct just before the extinction of C. cubensis Palmer in the lowest G. (G.) euape-tura zone—can be placed on the radiometric scale, Berggren<sup>8</sup> has recorded the extinction of C. cubensis, termed the 'Chiloguembelina extinction Datum', in about the middle of the Oligorene Globigerina angulisuturalis/Globorotalia (Turborotalia) opima opima zone which has been correlated with the type Chatian. Records of K/Ar dates on the type Chattian<sup>8</sup> of the North German Basin give a range of 28.8-31.2 ± 1.5 Myr BP, and Berggren<sup>8</sup> has placed the extinction of C. cubensis at 28 Myr. Supporting evidence for this date has come from an examination of basalts in Victoria, Australia<sup>9</sup>, similarly dated at 26.5-27 Myr BP, which were interpreted as having been emplaced somewhat later than the locally recorded extinction of C. cubensis.

Thus, accepting the validity of the radiometric dates and the correlation of the extinction level of C. cubersis, the initiation

Nature Vol. 2 November 29 1974

of the protobircum-Antarctic current probably occurred between 27 an 28 Myr BP and that event was followed by the eastward migraon of G. stavensis.

I thank C. J. Fleming, J. Kennett, K. Swanson, and L. Leonard for ho and comments, and N. de B. Hornibrook for providing acces to the New Zealand record of G. stavensis.

#### Advance of the Greenland Ice Sheet on to north-eastern Ellesmere Island

GEOLOGICAL evidence suggests that an important restricted ice advance occurred along north-western Greenland and north-eastern Ellesmere Island during the last glaciation.

Information on past ice margins is critical to the understanding of ice cores, delimitation of refugia, and preservation of both glacial and marine features that span several glaciations. It is widely assumed that during the last glaciation the Greenland Ice Sheet reached north-eastern Ellesmere Island1,2. It has also been assumed that during the last glaciation the ice sheets over northern Ellesmere Island and north-western Greenland coalesced to form a ridge 700-800 km wide centred over Kane Basin with outlet ice draining to the north-east and south-west along the line of Nares Straits. As yet, however, little geological evidence has been collected along these ice margins in relation to ice cores, and important existing literature has been ignored4.5.

North-eastern Ellesmere Island and north-western Greenland are separated by a distance varying from only 40 km to 130 km (Fig. 1). On north-eastern Ellesmere Island a major centre of ice dispersal exists over the United States Range where piedmont glaciers descend southwards along the northern edge of the Hazen Plateau. The southern margin of the active, United States Range Icefield is only 150 km to the north-west of glaciers from the Greenland Ice Sheet. The Hazen Plateau extends another 75 km to the south-east where it terminates directly across from Polaris Promontory, north-western Greenland. Physiographically, therefore, the region around the Hazen Plateau and the Polaris Promontory represents a relatively open area for the former interaction of the Ellesmere Island and Greenland ice sheets (Fig. 1).

Taylor<sup>6</sup> proposed that northern Ellesmere Island was once covered by the Greenland Ice Sheet, but this was rejected by Smith<sup>7</sup> on the basis of the distribution of Ellesmere erratics near the summits of the United States Range (Fig. 1). Christie8, however, noted the presence of red granite and gneiss erratics on Judge Daly Promontory and along the eastern edge of the Hazen Plateau, and suggested that a minor extension of the Greenland Ice Sheet on to north-eastern Ellesmere Island occurred at some unknown time in the past (Quaternary or Upper Tertiary glaciations?).

Red granites are exposed in Inglefield Land, north-western Greenland, and also amongst the moraines of Polaris Promontory8 and the glacial deposits south of Independence Fiord, in north-eastern Greenland. The hypothesis that the red granites were deposited by the Greenland Ice Sheet, which was possibly confluent with the south-eastward moving Ellesmere Island Ice Sheet over the eastern edge of the Hazen Plateau, implies that the granite erratics fall within a contained boundary. No detailed information yet exists, however, on the regional presence or absence of granite erratics over larger areas of northern Ellesmere Island.

Granite and gneiss bedrock has also been observed on the extreme northern coast of Ellesmere Island, and additional outcrops may extend inland beneath the United States Range Icefield. These would then coincide with the maximum, measured Pleistocene ice thicknesses over northern Ellesmere Island; and the southward movement of ice7 may thus have deposited these erratics on the outer Hazen Plateau and Judge Daly Promontory. This alternative hypothesis of a northern Ellesmere Island provenance is speculative and does not preclude the possibility that the Greenland Ice Sheet could have deposited the erratics8. Assuming that the red granite erratics on Ellesmere Island are products of the Greenland Ice Sheet then the remaining question concerns the timing of this ice advance.

Along the southern margin of the Hazen Plateau a discontinuous system of moraines marks the terminal position of ice draining out of the United States Range during the last glaciation<sup>10</sup> (Fig. 1). This system, termed the Hazen Moraines<sup>10</sup>, is associated with a maximum date of  $8,130\pm200~\text{BP}$  and is correlative with the Cockburn Stade of eastern Baffin Island11. Another till, of unknown age, extends above and beyond the Hazen Moraines and was deposited by an advance of the north-eastern Ellesmere Island ice out to Robeson Channel (Fig. 1). Shells adjacent to a coastal moraine, which is correlated with this till, date at 27,950±5,400 BP. This date, and the advanced surface weathering on a nearby ice-contact terrace, suggest that the advance may predate the last glaciation on northern Ellesmere Island. This most extensive northern Ellesmere Island ice advance is referred to as the Defosse Glaciation10. The preservation and lack of overriding of its coastal moraine and ice-contact terraces, suggest that any advance of the Greenland Ice Sheet on to north-eastern Ellesmere Island would have to predate the Defosse Glaciation.

In Inglefield Land (Fig. 1) there are three distinct glacial advances4. The oldest till (Stage 1) is the most extensive and reaches out to Kennedy Channel. It is characterised by ironstained, silicate rocks, and limestone boulders with solution cavities. The Stage 1 till is possibly correlative with the advance of the Greenland Ice Sheet on to north-eastern Ellesmere Island<sup>4,8</sup>. The Stage 2 till, less extensive than the Stage 1 till, is oxidised to a depth of one metre. Stage 3 defines the least extensive and most recent ice advance on Inglefield Land and is marked by a semicontinuous moraine system. A large terrace, possibly contemporaneous with, or older than, the Stage 3 ice advance, contained an organic layer dated at  $20,800\pm2,900$  BP. The distribution and relative ages of the three glacial stages on Inglefield land, therefore, indicate that a minor advance took place in this locality during the last glaciation and that the advance of the Greenland Ice Sheet on to north-eastern Ellesmere Island would have to be as old as Tedrow's Stage 1

Davies also notes at least three glaciations on northern Greenland during the Pleistocene<sup>5</sup>. The oldest glaciations are believed to be pre-Wisconsin in age and successively less extensive toward the present. Two stages of glaciation occurred on Polaris Promontory and again the oldest is the most extensive and is considered to pre-date the latest Würm-Wisconsin glaciation<sup>5</sup>. Karlstrom also suggests (personal communication) that low levels of glacial intensity occurred during the last major glaciation over Polaris Promontory. He adds that the Greenland ice may have approached, but not merged with, the Canadian ice during the

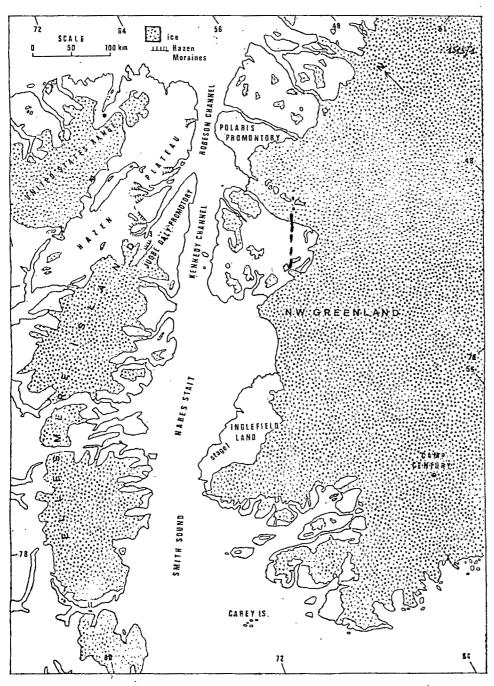

Fig. 1 Mp of area covered by the Greenland IoSheet.

last one or two major glaciations. The restricted position of the Hazen Moraines, and the preservation of the features from the Defosse Glaciation on north-eastern Ellesmere Island, supports that suggestion.

Bendix-Almgreen et al<sup>12</sup>, working on the Carey Islands, 110 km off the coast of north-western Greenland (Fig. 1), conclude from the distribution of erratics that the Greenland Ice Sheet formerly extended out to and beyond that area. They<sup>12</sup> suggest that Nares Strait was probably completely filled with the Greenland and Ellesmere Island ice sheets during the full-bodied stage of the Wisconsin. The date of deglaciation of the Carey Islands is not known although it may predate the age of shells from Saunders Island, 25 km off the coast of north-western Greenland, which date at more than 32,000 years BP (ref. 13). This date is probably a minimum age estimate on the last retreat of the Greenland Ice Sheet from Smith Sound. The available geological evidence and climatic considerations<sup>14</sup> along Smith Sound, Nares Strait and Kennedy and Robeson channels does not support the conclusions

that towards the end of the last glaciation the north-western Greenland Ice Sheet was 1,300 m thicker than today<sup>15</sup>.

High coastal marine limits (>120 m) have also been interpreted as evidence for an extensive ice advance in that region during the last glaciation. The interpretation is, however, based on the assumptions that the marine limits are all postglacial features and that all these features represent a glacio-isostatic response related to a very extensive ice advance. As yet, however, there are no radiocarbon dates on these high coastal marine limits and the observed postglacial uplift over north-eastern Ellesmere Island and north-western Greenland can be reproduced by an uplift model<sup>16</sup> using the restricted ice margins discussed in both areas<sup>5-10</sup>.

Present evidence indicates that detailed records of multiple glaciations and sealevel changes are preserved along the coastlines of Smith Sound, Nares Strait and Kennedy and Robeson channels. There should, therefore, be stratigraphic evidence on the magnitude and age of the proposed advance of the Greenland Ice Sheet on to north-eastern Ellesmere Island

as indicated if the preservation of the oldest, subsequent ice advances in bh areas. The same information applies to the stratigraphic d chronological clarification of the proposed Greenland-Elimere Island ice-ridge over Kane Basin.

At present he advance of the Greenland Ice Sheet on to north-easternillesmere Island is considered inconclusive and, if it did occul it would have to pre-date the late Wisconsin, and possiblythe entire Wisconsin glaciation. The possible presence of lisconsin refugia on northern Ellesmere Island<sup>17</sup> is considered on sistent with the geological evidence 10.

Evidence bm glacial geology is also critical for the reconstruction of se time profiles through existing and future ice cores in the reion as such data will affect directly the parameters in the flow midels chosen. If the ice sheets in the High Canadian and Greenlad Arctic were relatively inactive during the last glaciation or laciations then the ice cores obtained from these areas may bolder than originally expected. Sections in the ice cores18 tat indicate conditions colder than the present may coincide ith glacial inactivity which resulted from a more continental emate, whereas the warmer sections in the cores may reflect mre maritime (glacial) conditions. The chronology of glacial activity during the late Quaternary is, therefore, an important sorce for both the dating and palaeoclimatic interpretation of te ice cores.

#### **Exfoliated pebbles** and sheeting in the Triassic

SHATTERED pebbles and sheeted bedrock are common weathering phenomena in most modern deserts1-3 but their existence in ancient desert environments does not seem to have been described. This communication documents their occurrence in South Wales, where they were formed during the Triassic period, some 200 Myr ago.

Two facies are developed in the Upper Triassic of South Wales4.5-the Keuper Marl, a purplish-red dolomitic silt, which is considered to have formed in a hypersaline lake or inland sea6-8, and the 'littoral' or marginal Triassic (wherein the weathering phenomena occur), red beds of variable lithology and facies, which occur below and laterally equivalent to the Keuper Marl. Environments and landforms represented by the marginal facies in Glamorgan include alluvial fans9 and plains, pediments, wadis10, playas and soils. The deposits of these environments (fanglomerates, calcarenites, playa silts, lacustrine cryptalgal laminites, fenestral (birdseye) limestones and calcretes) accumulated against and below a retreating Palaeozoic mountain front and around monadnocks ("islands",4,5) mainly composed of Carboniferous Limestone.

Many limestone pebbles on the surface of a conglomerate, exposed at Hayes Point near Barry (Grid Ref. ST143674) are completely shattered (Fig. 1). Some pebbles have fractured to a perfect onion-skin pattern, consisting of concentric spheres of rock, split a few millimetres apart. Other pebbles have simply shattered into several angular slices. Cracks in pebbles are infilled with red silt and sand, except where the cracks have penetrated a few centimetres below the former land surface, when they are now filled with calcite. The conglomerate (110 cm thick) is a moderately sorted mixture of limestone pebbles and sand, with an irregular and deeply scoured base. It was clearly deposited relatively quickly (hours or days) and is probably the product of stream flooding. A prolonged period of weathering followed deposition of the conglomerate, when the surface pebbles were shattered and exfoliated.

At Bendrick Rock (Grid Ref. ST131668) the Triassic red beds abut against and then overlie Carboniferous limestone which must have formed a small monadnock or knoll, rising out of

Fig 1 Exfoliated pebble of Carboniferous limestone, with concentric (onion-skin) fractures, in red Triassic sandy dolomite. Hayes Point, Glamorgan.

the Triassic pediment. The surface of the Carboniferous limestone, down to 30 cm, is split into thin sheets, parallel to the former surface. Red silt, probably of aeolian origin, occurs between the sheets. Fossils and ooliths in the limestone are truncated by the cracks. The sheeting clearly developed upon the former surface and not within a weathering profile. Other features at and just below this weathered surface include neptunian dykes and an iron-staining pattern around joint blocks in the Carboniferous limestone. Calcretes (of which at least 12 occur) interbedded with red marls are developed against the Carboniferous limestone monadnock on which the sheeting is developed, and probably formed at the same time. Calcretes (pedogenic limestones) represent periods of soil formation which lasted the order of 5,000 to 30,000 yr11. This suggests that the sheeting of the bedrock surface developed during a considerably longer period of time (104 to 105 yr).

Much debate has been concerned with the origin of shattered pebbles and exfoliated surfaces in modern deserts1.3, Experiments by Blackwelder<sup>12,13</sup> and Griggs<sup>14</sup> demonstrated that a purely physical process of repeated temperature changes did not result in rock disintegration, but that some degree of chemical weathering (even just the presence of water) was required. Records<sup>15,16</sup> of fractured pebbles of nearly chemically inert flint and quartzite do, however, suggest that insolation alone can be effective. The occurrence of frost-weathering in deserts has been realised only recently and could also be an effective cause of rock shattering, especially in higher altitude deserts, during cooler climatic phases1,17. Crystallisation of salts within confined spaces18 (such as cracks along joint, cleavage and bedding planes) leads to rock disintegration. This is a common phenomenon in arid (and coastal) environments19,20, particularly on saline playas, along alluvial fan channels21 and on high tidal flats22. Precipitation of calcite during surface calcretisation can have a similar rock-splitting effect<sup>23</sup>.

In these Triassic examples of exfoliation, there is no evidence of contemporaneous chemical weathering, such as karst and solution structures, although pebbles and rock sheets are commonly dolomitised (probably a post-Triassic diagenetic event). No evidence has been found for the presence or former existence of salt deposits or their replacements at the exfoliated horizons, although salt efflorescences could conceivably have been dissolved following deposition of the overlying beds. Evaporites do occur higher in the succession (some 100 m above) towards the top of the Keuper Marl. Salt weathering, however, seems to produce linear fractures and flakes of rock21,22 rather than the concentric type of fracture illustrated in Fig. 1. Calcite of calcrete (pedogenic) origin does not occur within cracks—these are filled with clastic sediment or sparite druse. It would seem then that the exfoliation structures formed primarily through isolation, although water (from precipitation) or dew24 may have been a contributory factor. In view of the Rhaetic marine transgression towards the end of the Triassic period, it is likely that this part of South Wales was a low altitude desert area during this time, where frost action would rarely occur.

The presence of exfoliated pebbles and sheeted bedrock is evidence additional to that provided by aeolian dune-bedding, millet-seed sands, ventifacts, calcretes and evaporites for an arid or semi-arid climate during the Triassic period in Britain. Paleomagnetic data support this deduction by indicating a low palaeolatitude (10-30 °N) for Britain during the Triassic25.

#### Diverse microfossils in Precambria Onverwacht group rocks of South Ifrica

We report the discovery of some complex micofossils from the Kromberg formation of the Onverwacht goup of South Africa. The samples, in which the microfossil were found, were collected by D.O.H. along the banks of the Komati River in the Barberton Mountain Land, at Skapbrug, near the old JCI mining camp. The Kromberg fomation lies in the Upper part of the Onverwacht group, above the Middle Marker Horizon, which has been dated as  $3.35 \times 10^9$  yr old<sup>1</sup>. The Onverwacht group is the oldest member ofthe Swaziland Supergroup and lies below the  $3.1 \times 10^9$  yr old: ig Tree group. Microfossils have been reported from the FigTree group2,3, and simple spherical and filamentous forms from the Onverwacht4-6. Spherical and cup-shaped carbonceous microstructures have been reported7-9 from the Overwacht but were not regarded as biogenic in origin.

The present forms are more complex than these previously described4-6; they were discovered in petrological thin sections and include spheroids, filaments and agglomerations of cells. Although spheroids have previously been decribed, those from the Kromberg formation<sup>5</sup> fell within a narow size range 15-20 µm (Fig. 1a). In the present samples, more cells of the same size have been discovered but smaller cills ranging in diameter from 3 µm to 7 µm have also been found (Fig. 1b), having a relatively thick wall (0.5-1 µm thick) and often black or very dark brown in colour. Although mainly found solitary and not associated with other organic matter, they are occasionally paired.

The filaments in the thin sections are of three types: (i) filaments similar in dimensions and morphology to those previously described<sup>5</sup>; (ii) small (diameter 1-3 μm, length up to 25 μm; Fig. 1c), non-septate filaments; (iii) segmented filaments (diameter 1.5-4  $\mu$ m, length up to 42  $\mu$ m, and with individual cells of diameter 1.5-4  $\mu$ m and length 2-5  $\mu$ m; Fig. 1d).

Large numbers of cells of uniform size (diameter 3-8 μm) occur associated, set in a matrix of amorphous organic matter, on average 5-10 µm apart (Fig. 1e).

In two samples, very rich in organic matter, we found what appears to be multicellular tissue. This is composed of very large numbers of cells of more or less uniform size (7-10 µm; Fig. 1f). These cells are approximately equidimensional and

their overalbutline is modified by the presence of adjacent cells, that ishey appear to have walls in common with adjoining cells to distinct overall outline to these agglomerations of cells is dismable, the maximum diameters of single agglomerations rankg up to more than 200 µm. Some of the agglomerationshave a rounded outline, while others enclose areas of wateclear chert, free of organic matter.

The large/ariety of morphologies and the number of individual spimens leads us to the conclusion that the structures observe are biogenic in origin. Their state of preserva-

Scale bar represents approximately 5 µm (all micrographs).

tion is variable, depending on the degree of metamorphism of the sample, but allowing for the carbonisation which has taken place<sup>5,10</sup>, the morphology of the fossils is distinct and can be compared with the morphologies of specimens from younger rocks11-14. The morphologies found—spheroids, single or paired, filaments, segmented or nonsegmented, 'colonial' structures where single spheroids occur associated, set in a matrix of apparently mucilaginous material, and multicellular structures—have all been described from prokaryotic groups such as the blue-green algae, and some of the bacteria.

There is ample evidence for the presence of biological activity in Archaean rocks. Stromatolites have been described from Rhodesia<sup>15</sup> in rocks now dated at 3.1 × 10<sup>9</sup> yr old<sup>16</sup>, and from the Canadian Shield17 in rocks more than 2.7 × 109 yr old18. Schopf et al.15 believe that the discovery of the Rhodesian stromatolites indicates the activity of blue-green algae but stromatolites have been described from hot springs19,20 in which photosynthetic bacteria play an important role. Doemel and Brock<sup>21</sup> were able to demonstrate that in the hot spring deposits at Yellowstone National Park photosynthetic bacteria control the lamination of the mat structure as a response to light fluctuations. The organism present is Chloroflexus, a filamentous photosynthetic bacterium which acts as a sediment trapper; it produces a laminated siliceous sediment in which the laminae are of variable thickness and where, under the regions rich in organic material, laminated silica is preserved. In the modern sediment, blue-green algae are also present to varying extents depending on the depth of the layers where light intensity may be the controlling factor. Chloroflexus cells are much more resistant to degradation than blue-green algae and bacterial remains are the most abundant. Although the blue-green algae virtually disappeared at low levels in the mat, however, they could still have played a role in its formation. Their results21 "show that stromatolites might have been formed solely by filamentous photosynthetic bacteria".

All the Onverwacht cherts studied from the Kromberg formation are finely banded with bands rich in organic material alternating with those which are poor in such. This forms the bulk of the rock studied, even when no structurally preservable microfossils can be observed. Such banded rocks are generally the result of biological activity, whether they be bacterial or algal mat structures, or glacial varves.

Thus, although the present discovery of microfossils supports the hypothesis that quite diverse remains of biological activity can be detected in the rocks of the Onverwacht group, there is at present no way of determining their biological affinities.

In light of recent work with photosynthetic bacterial stromatolites and mat structures it is possible that the microfossils we are examining are the remains of a similar type of mixture of organisms in the modern laminated mats.

We thank Dr C. Anheusser, of the Economic Geology Research Unit, University of Witwatersrand, Johannesburg, for advice on sampling locations and rock identification and Mr R. Friedericksen for help with sampling.

#### Reliability of amino acid racemisation dating and palaeotemperature analysis on bones

THE general inability of isotope geologists to work out techniques for dating continental Pleistocene deposits has led to the conception of nonisotopic chemical methods. Hare and Mitterer1 noted that fossils could possibly be dated by determining the extent to which the l optical isomer of a given amino acid had racemised to form the d isomer which is initially absent in skeletal material. Obviously, the rate constant for the reaction must be known accurately if age is to be calculated, but its value is difficult to assess: it is highly temperature dependent<sup>2</sup> (about 20% ° C<sup>-1</sup>); it depends on the state of the amino acids (free amino acids racemise about an order of magnitude more rapidly than those bound as peptites)3-5; and it is highly dependent on environment<sup>6</sup>. Furthermore, free amino acids may back react to produce the bound forms, and there could be open system conditions during diagenesis2.

Bada et al. have investigated amino acid racemisation geochemistry as a method of dating fossil bones<sup>2</sup> and as a means of deducing palaeotemperature data where ages have been independently determined. They showed that 'ages' or 'palaeotemperatures' calculated from data of racemisation of amino acids in Upper Pleistocene bones are generally comparable to independently deduced values. That does support the notion that racemisation may be useful in geochronological and palaeoclimatic evaluations, but their results have many inconsistencies.

Bada et al.2 determined the extents of lacisation of amino acids in two or three year old bone fragmts collected in the Arizona desert. From the observed exteniotcemisation of glutamic acid, and the temperature dependen of the rate constants, it is possible to calculate that the saple was preserved at an average temperature of about 1.C. That is however, completely unlikely. A more reasonablexplanation for the anomalously large degree of racemision is that there is a brief interval after the death of the orgism, during which racemisation proceeds more rapidly that does later in the history of the fossil. If that is actually e case then 'ages' or 'temperatures' which are calculated y assuming constant racemisation, may be quite misleading.

Moreover, the rate constant, normalised to a /en temperature, is extremely sensitive to the environmentn particular, the extent of isoleucine racemisation (actually)imerisation) in bone from La Brea tar pits was found to be nch less than expected from data on isoleucine racemisatio on samples from Muleta Cave and elsewhere<sup>6</sup>. This is appantly because of the relatively anhydrous environment proded by the asphalt in which the La Brea sample was preserd.

Turekian and Bada<sup>7</sup> have established a hronological sequence in a section from Muleta Cave in allorca from radiometric and isoleucine racemisation ages (& latter were calculated by assuming that the temperature tere has been constant at 19° C and that the rate constant athis temperature is  $6 \times 10^{-6}$  yr<sup>-1</sup>). Their results show that amo acid dates and 230Th dates agree (the 14C dates are muchyounger, but that is probably because whole bone was analyse, rather than just the collagen fraction8). Bada9 has redeterined the rate constant, and his recent results give a value of  $16 \times 10^{-6} \text{ yr}^{-1}$ at 19° C (this value is also similar to that estimted using the rate constant for aspartic acid, calculated for the 8,600 yr old Muleta sample7, and the ratio of rate constant for aspartic acid and isoleucine racemisation2). Ages recaulated using this value of k are lower than previously calculate racemisation ages by more than a factor of two, and are inonsistent with <sup>230</sup>Th/U ages (Table 1).

Bada has also established a chronology from the Z section of Muleta Cave (Table 2). It is clear from thee results that the 14C ages on bone collagen fraction, the amino acid chronology, and the 230Th chronology are all strongly discordant. This apparent discordance becomes even greater when k is modified to account for the facts tha temperatures were generally lower than 19° C and that it was the collagen fraction, which racemises more slowly than thewhole bone<sup>10</sup>, which was sometimes analysed.

Table 1 Calculated age sequence from X sector in Muleta Cave*								
Position in section (cm)	Nature of sample	Dating technique	Calculated age (yr)					
80	Travertine	<sup>230</sup> Th	85,000 and 97,000					
95	Collagen fraction of bone	Isoleucine racemisation	180,000					
200	Collagen fraction of bone	Isoleucine racemisation	280,000					
250	Bone	Aspartic acid racemisation						
300	Whole bone	14C	16,400					
350-400	Whole bone	<sup>14</sup> C	18,735					

<sup>\*</sup> Isoleucine racemisation ages are calculated using  $k = 2.6 \times 10^{-6} \text{ yr}^{-1}$ .

<sup>\*</sup> Calculaterom the results of Bada et al.2, k by assuming the d isomer to be absent in modern specimens. Errors in the rate constant ratios are estimated:  $\pm 20\%$  using the analytical uncertainty ( $\pm 10\%$ ) in the gas chromatographic analyses of the d/l ratio (K. A. Kvenvolden, personal comunication).

Schroeder nd Bada<sup>10</sup> determined the extent of aspartic acid racemision in 14C dated bones (see also ref. 2), and used the relts to calculate palaeotemperature histories. Using reasorble assumptions they calculated that the temperature in Juleta Cave was about 4°C colder between 10,000 and 1000 years ago than it is at present, a conclusion consistent wa most other evidence. Using their data and approach to liculate the average Muleta temperature between 19,000 and 2900 yr BP (sample 1704A) it is possible to estimate that temperaires during that period were similar to those at present. Nost other evidence, including that summarised by Schroede and Bada, indicates, however, that during that period the temperature was much cooler than at present. The difference can be reconciled if it is assumed that the 14C age is wrong but such an assertion would undermine other conclusions.

Bada et al. determined rates of racemisation of amino acids in bones heatd at elevated temperatures in laboratory experiments. They jointed out that if a given sample has not been altered by opn system conditions, then the relative extent of racemisation of the different amino acids must be consistent with the relaive extents predicted from the rate constant data. That is an important observation because it allows a check on wheher or not the sample has been a closed system. The check can be applied by using the ratios of optical isomers for the various samples to calculate ratios of rate constants for the various anino acids, so that the results can be compared with those predicted from the high temperature heating experiments of Bada et al.2 (Table 3).

For all samples at least one of the calculated rate constant ratios is inconsistent with the predicted value (Table 3), so all of these samples have suffered some contamination. Different samples seem to be contaminated with different amino acids. In my opinior no meaningful conclusions of palaeotemperature or palaeoclimate can be deduced from any of these results.

The contribution from Bada et al.2 is very significant in that it outlines quantitative, a priori, criteria for determining if amino acid tacemisation ages or temperatures are reliable. Their findings, and the fact that reasonable ages and temperatures are sometimes obtained, indicates that the method has potential. It dearly faces many basic problems, however, and in my opinion no palaeoclimatic or geochronological inferences should be drawn from racemisation data until the basic geochemistry is thoroughly understood and the bases of the method firmly established.

This work was supported financially by National Science Foundation. I am grateful to Drs W. S. Broecker, K. K. Turekian and J. Wehmiller, for reading the manuscript.

DR BADA REPLIES-Bender's review of my work is both inaccurate and incomplete. He has not cited two of my publications dealing with aspartic acid racemisation dating1,2. (Although one paper was only recently published, I sent Bender a preprint the first of this year when he informed me he was writing a review.) In those articles I show that after 'calibrating' the amino acid racemisation reactions using a radiocarbon dated bone, it is then possible to date other bones from the same site, which are either too old or too small for radiocarbon dating. The only assumption in this approach is that the average temperature experienced by the calibration sample is representative of the average temperature experienced by the other sample. Ages thus deduced are in good agreement with radiocarbon ages determined on the same samples2.

Bender points out that several factors (temperature, protein hydrolysis, and so on) can influence the extent of amino acid racemisation in a fossil. I am fully aware of these factors and have discussed the potential limitations of racemisation dating which arise from each of them<sup>3-5</sup>.

The bovine bones discussed by Bender were found lying on the surface in the desert plateau region of south-western Arizona3. They were collected because I wanted modern bone samples for kinetic studies of isoleucine epimerisation in bone. The samples seemed ideal, as they had already experienced the early phase of animal bone diagenesis (that is, carnivore and microbial consumption of the adhering flesh). The low alloisoleucine/isoleucine ratio (0.02) indicated the bones were not very old.

Following the isoleucine studies, an analysis of the extent of racemisation of aspartic acid in the desert bones was carried out, and this indicated a d/l ratio of 0.15 (ref. 4). An analysis of a piece of bone from a beef steak, however, yielded a d/laspartic acid ratio of 0.07 (ref. 1). That value is in close agreement with d/l ratios of aspartic acid found for several proteins carried through the same analytical steps as the bone samples<sup>6,7</sup>. A d/l ratio of 0.07 must, therefore, represent the t = 0 value for aspartic acid.

The aspartic acid results suggested that the desert bones were probably older than the 2-3 yr originally estimated. To calculate an average temperature to which the bones have been exposed, as Bender has done, in the absence of firm documentation of their age, is unwarranted. Furthermore, although the present mean temperature in the region where the bones were found (Yuma, Arizona) is 22° C (ref. 8) ground temperatures as high as 80°-85° C have been reported (M. A. Barker, unpublished). An older age and the occasional ex-

<sup>&</sup>lt;sup>1</sup> Hare, P. E., and Mitterer, E., Yb. Carnegie Instn. Wash., 67, 205 (1969).

Bada, J. L., Kvenvolden, K., and Peterson, E., *Nature*, 245, 308 (1973).

tremely high temperatures could account for the extent of racemisation in the Arizona desert bones.

Bender contends that racemisation rates in bone are extremely sensitive to environmental factors other than temperature. He states that Schroeder and myself<sup>9</sup> also noticed this; we have never made this statement and would, in fact, strongly disagree with it. The rate constants of aspartic acid racemisation determined from the extent of racemisation in radiocarbon dated bones younger than 10,000 yr (post-glacial), all show a remarkable correlation with the present mean temperatures of the general regions in which the bones were found<sup>1,2,9,10</sup>. The same correlation exists for glacial age bones, but this should be considered less reliable, as temperature changes during the last ice age may have been different at the various sites. The sites we have studied range from temperate coastal to near tropical mountainous regions in Africa, and from hot, arid rock shelters in Iran and Iraq to a limestone cave on Mallorca. If environmental factors other than temperature had an important influence on racemisation rates, it would seem that the correlation between the rate constants and the average temperatures for these various sites would not be as good as it is.

The racemisation rates<sup>4</sup>,<sup>11</sup> for the bones from the La Brea Tar Pits are indeed anomalous. This type of environment is, however, rare and extreme. Racemisation rates determined from radiocarbon dated bones from the surrounding southern California area would hardly be expected to be applicable to the tar pits. In order to date the bones in the tar pits, a 'calibration' should be carried out by determining the extent of racemisation in a radiocarbon dated bone from the tar pits, and then other samples from the tar pits could be dated.

The isoleucine ages published by Turekian and myself for Muleta Cave<sup>12</sup> were only preliminary results, to show the possible potential of the racemisation technique. Detailed kinetic studies at elevated temperatures have yielded better estimates of  $k_{1so}$  at the Muleta Cave temperature<sup>3</sup>, and these  $k_{iso}$  values have yielded ages in reasonable agreement with radiocarbon ages<sup>3,4</sup>. Also, the allo/iso ratios in the Muleta Cave bones were very small (less than 0.1) and difficult to measure accurately. The isoleucine ages were only rough estimates.

We have obtained aspartic acid racemisation ages for Muleta Cave (ref. 2, and J. L. Bada, unpublished) (Table 1). When the radiocarbon age is based on the collagen component, it agrees excellently with the aspartic acid racemisation age. The racemisation age determined for the bone from the X section is, however, much older than the radiocarbon ages obtained from that section. This is not surprising, as the radiocarbon ages were based on the total acid-leached carbon.

	Table 1 Muleta Cave ages										
Cawe section*	d/l Aspartic acid	Aspartic acid agef (yr)	<sup>14</sup> C age (yr)								
Z-400 cm (UCLA 1704D)‡	0.273		16,850±200

X-250 cm X-300 cm (SI-648) X-350 to 400 cm	0.73	69,000	16,335±415 18,735±555								
(SI-650)			•								

<sup>\*</sup> Notation in parentheses is radiocarbon laboratory identification number. The UCLA results are collagen dates, whereas the SI ages are for acid leached carbonates. †  $k = 1.25 \times 10^{-5} \text{ yr}^{-1}$ .

Such ages are often unreliable because of exchae processes involving ground water carbonates of diffint specific activities<sup>13</sup>.

The aspartic acid age for bone from the 250 cm rizon of the cave X section suggests an age of about 100,00r artits base (the total section depth is approximately 400 c. The <sup>230</sup>Th age of the surface of a stalagmite around which the section formed was found to be  $85,000\pm8,000$  yr (ref. 1. This age is consistent with the age of 100,000 yr for the base the section, as it seems likely that carbonate accumulation the stalagmite would stop shortly after sedimentation in the tion began.

Schroeder and I<sup>9</sup> did not use sample 1704A inur temperature calculations because of the uncertainties in themperature model for the Mediterranean area at 20,0000,000 yr BP. Also, the radiocarbon age of this sample is probal less reliable than that of the other radiocarbon-dated samplerom Muleta Cave, as it was collected from an horizon 50 cmick whereas the other samples were obtained from more disete horizons. Thus, the radiocarbon age represents an 'avege' over the 50-cm section. The racemisation analysis was tried out on a single 10 g piece which could have an age slittly different from the 'average' radiocarbon age.

Using the procedure outlined by Schroeder id myself<sup>9</sup>, I calculate that the difference between the averagtemperatures experienced by samples 1704C and 1702A (stable 1) is  $-0.8^{\circ}$  C, compared with the difference of  $-1.6^{\circ}$  experienced between 1704C and 1704D. Evidence<sup>9,14</sup> indicateshat there was a period of gradually increasing temperature between  $\sim 20,000$  and 50,000 yr BP, although temperatures never riched present values. Some of the coldest temperatures during he last glacial occurred at about 15,000–20,000 yr BP (ref. 1). Therefore, a bone of about that age (such as 1704D) wouldield a slightly cooler average temperature than a bone with ange of around 30,000 yr (such as 1704A).

Because the relative rates of amino acidracemisation determined by heating modern bone fragmens at elevated temperatures are not exactly the same as those i fossil bones, Bender believes that all fossil bones analysed b Kvenvolden, Peterson and myself4 were contaminated to some degree with modern amino acids. Although the Arrhenius ativation energies  $(E_a)$  are about the same for the variou amino acid racemisation reactions, they certainly differ by atleast tenths of a kcalorie per mol (the experimental uncertainties of the  $E_a$  values). This difference is not enough to chinge the order of racemisation rates (that is, aspartic acid > alanine \( \sime \) glutamic acid > leucine \( \Leftrightarrow \) isoleucine) in goingfrom elevated to lower temperatures, although it could causesmall changes in the relative rates. For example, if any two reations have  $E_a$ values of 33.0 and 32.0 kcalorie mol-1 and the ratio of the rate constants is 5:1 at 100°C, then at 20°C the ratio would have changed to 3.5:1. Thus, the relative rates of racemisation in uncontaminated fossil bones coud be different from those found in modern bones heated at elevated tempera-

Bender (his Table 3) shows that the relative racemisation rates for bones from Muleta and Border Caves are essentially identical (within experimental error). As these two bones differ considerably in age and in depositional environment, I suggest that this similarity, in fact, indicates that these bones are not contaminated and that the relative rates of racemisation observed represent the pattern expected in uncontaminated bones. Other samples in Bender's Table 3 are contaminated to various degrees, a point which I have emphasised before.

Bender seems to have missed the point that even if a bone is contaminated, racemisation can still provide a minimum age. Contamination introduces amino acids that are more modern (that is, consist of mainly the *l*-enantiomers) than the indigenous collagen-bound amino acids, and therefore lowers the *d|l* amino acid ratios.

I thank C. Lee and R. A. Schroeder for review of the manuscript. This work was supported by the National Science Foundation.

#### Theory ofliquid—liquid and liquid-va our equilibria

We formulat here a general molecular theory of solutions, which predic a first order phase transition (boiling), volume changes on rixing, and the complete phase behaviour of pure and mixed flids. Our formulation is based on a simple hole theory of theliquid state.

The total gange in the Gibbs free energy that is associated with the creation of  $N_0$  holes in a liquid of  $N_1$  molecules of size

$$\Delta G = \left[ v_1 N_0 E_h + P N_0 v_h + R T [N_0 \ln v_0 + N_1 \ln v_1] \right]$$
 (1a)

or, in reduced variables, by

$$\Delta G/rN_1E_h = G - G^0$$
=  $(1-1/v) + P(v-1) + T[(v-1)\ln(1-1/v) + (1/r)\ln(1/v)$  (1b)

where, r = hard core molecular volume/hole volume,  $v_h$ ;  $v_o = 1 - v_1 = N_o/(N_o + rN_1)$  = volume fraction of holes;  $\varepsilon$  = intermolecular interaction (contact) energy;  $E_h = \gamma \epsilon/2 = \text{hole}$  energy;  $\gamma = \text{lattice}$  coordination number;  $P = P \nu_h / E_h = \frac{1}{2} (E_h + E_h)$ reduced pressure;  $T = RT/E_h = \text{reduced temperature}$ ; V = macroscopic volume;  $V_o = rN_1v_h = \text{hard core volume}$  of molecules;  $\mathbf{v} = V/V_0 = 1/v_1 = \text{reduced volume}$ ;  $\mathbf{G}^0 = -1$ +P = reduced free energy of liquid without holes.

Equation (1) can be obtained directly from a lattice model in which the partition function is evaluated in the mean field approximation. It can also be obtained without appealing to a lattice description of the liquid state1.

The equilibrium number of holes can be determined by minimising the free energy with respect to  $N_o$ , or equivalently, the reduced volume v. Thus:

$$(\partial \mathbf{G}/\partial \mathbf{v})_{\mathbf{T}, \mathbf{P}, N_1} = 1/\mathbf{v}^2 + \mathbf{P} + \mathbf{T}[\ln(1-1/\mathbf{v}) + (1-1/r)(1/\mathbf{v})] = 0$$
(2a)

or

$$\frac{1/\mathbf{v} = f(1/\mathbf{v})}{= 1 - \exp[-1/(\mathbf{T}\mathbf{v}^2) - (1 - 1/r)(1/\mathbf{v}) - \mathbf{P}/\mathbf{T}]}$$
(2b)

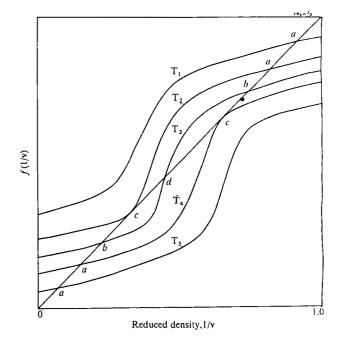

Fig. 1 Schematic representation of the graphical solution of the equation of state, equation (2b), below the critical point. The pressure is held constant and the temperature is varied. The various solutions to the equation of state produce the following kinds of behaviour in the Gibbs free energy, G: points a, absolute minima; points b, relative minima; points c, inflection points; points d, relative maxima.  $T_1 < T_2 ... < T_5$ .

The equation of state (2a or b) coupled with equation (1) defines the Gibbs potential in terms of its natural variables, T and P. Thus, all thermodynamic properties of the model are determined. Note that equation (2) is to be interpreted as defining the volume v in terms of T and P. This is an important distinction which assures that G will always be defined in terms of its canonical variables T and P; this further ensures that thermodynamic oddities, such as negative pressures, or compressibilities, will be avoided.

Equation (2b) can be solved graphically (Fig. 1). The pressure is held constant and the temperature is varied. At the lowest temperature, T1, only one solution to equation (2) exists (point a) and it corresponds to a high density phase (liquid). Point a corresponds to an absolute minimum in G. As the temperature is increased to T2, a second solution appears at the tangent, point c, which corresponds to a low density phase (gas). A corresponding inflection point occurs in G at point c whereas an absolute minimum in G still occurs at the new point a. At a temperature T<sub>3</sub> slightly above T<sub>2</sub>, there are three solutions to equation (2): two of them (points b) correspond to relative minima in G and the third (point d) yields a relative maximum in G. Thus, at temperatures near T3 both liquid and gas phases are possible and, in general, one phase will be metastable with respect to the other. At T4 the last vestige of a liquid phase is seen (metastable limit for liquid phase), and by  $T_5$  only a low density gas phase is present. There is a unique temperature, near T3 at which the free energy minima will be equal; this is the equilibrium saturation temperature. In the pressure-volume plane the locus of all such points define the classical saturation curve (binodal) (Fig. 2), and the locus of all the tangent points c defines a metastability limit (spinodal) (Fig. 2).

The spinodal is determined from  $\partial f(1/v)/\partial (1/v) = 1$  and equation (2) which defines the tangent points c (Fig. 1), and

$$P_{s} = -\frac{2v_{s}(v_{s}-1) \ln(1-1/v_{s}) + (1-1/r)(v_{s}-1) + v_{s}}{v_{s}^{2}[v_{s}-(1-1/r)(v_{s}-1)]}$$
(3)

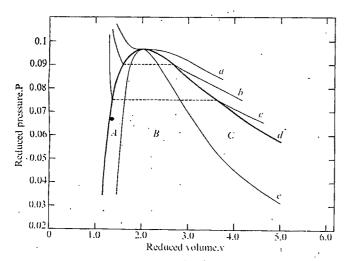

Fig. 2 Theoretical Pv diagram of a fluid for which the ratio of the hard core volume of the molecule to the hole volume is unity (r = 1). Along the equilibrium saturation curve (binodal), the Gibbs free energy, G of the liquid and gas phases are equal. The metastability limit (spinodal) is determined by equation (3). The set of all P, v points in the unstable region B yield relative maxima in G; G is nonanalytical (essential singularity) at the critical point. Tie lines connect isothermal states on the binodal, but not on the spinodal; spinodal temperatures are determined by equation (4). a, T = 0.500; b, T = 0.483; c, T = 0.455; d, equilibrium saturation curve; e, metastability limit. A, Metasstable liquid; B, unstable; C, metastable vapour.

for  $\mathbf{v}_s^0 \le \mathbf{v}_s < \infty$ ; where,  $\mathbf{v}_s$  and  $\mathbf{P}_s$  are the reduced volume and pressure that define the spinodal in the Pv plane (see Fig. 2), and  $\mathbf{v}_s^0$  is the value of  $\mathbf{v}_s$  for which  $\mathbf{P}_s = 0$ . The reduced spinodal temperature, Ts, is given by

$$T_s = [2(1-1/v_s)]/[v_s - (1-1/r)(v_s - 1)]$$
 (4)

The critical point not only satisfies equation (3), but also  $\partial^2 f(1/\mathbf{v})/\partial(1/\mathbf{v})^2 = 0$ . These conditions on  $f(1/\mathbf{v})$  are equivalent to the usual conditions for a critical point,  $(P_c, v_c, T_c)$ , that is,  $(\partial P/\partial V)_T = 0$ , and  $(\partial^2 P/\partial V^2)_T = 0$ , and they yield:

$$\mathbf{v}_c = 1 + \sqrt{r}; \ \mathbf{T}_c = 2r/(1 + \sqrt{r})^2$$
 (5)

$$\mathbf{P}_c = [2/(1+\sqrt{r})^2][r \ln(1+1/\sqrt{r}) + 1/2 - \sqrt{r}]$$
 (6)

Close examination of the equation of state shows that the free energy has an essential singularity at the critical point2.

The molar critical compressibility factor,  $Z_c$ , is given by

$$Z_{c} \equiv P_{c}V_{c}/RT_{c}$$

$$\equiv r(P_{c}v_{c}/T_{c})$$

$$= (1+\sqrt{r})[r\ln(1+1/\sqrt{r}) + 1/2-\sqrt{r}]$$
(7)

For  $r = 2, Z_c = 0.375$  which is identical to that obtained from the VDW and Berthelot equation of states3. The similarity of equation (2) and the VDW equation becomes more apparent when the former is expanded in virial form:

$$PV/RT \equiv r(Pv/T)$$
= 1+r(1/2-1/T)(1/v)+(r/3)(1/v)<sup>2</sup>
+(r/4)(1/v)<sup>3</sup>+...
(8)

The temperature dependence of the second virial coefficient is identical to that of the VDW equation.

Other observations are noteworthy. First, it is often assumed in hole theories that the total hole energy, E, is proportional to the number of holes  $(E = N_o E_b)$ . This is a valid approximation only at high densities. At low densities, hole-hole contacts become prevalent; when the random mixing correction for hole-

hole contacts is made, theenergy becomes  $v_1 N_0 E_h^{(l)}$  inificantly, if the v<sub>1</sub> factor is ignored, no phase transition will or. Second, the equilibrium saturation curve can be determd without appealing to the Maxwell construction or any otl construction outside thermodynamics. Third, the equate of state, equation (2a), implies a generalised correspoing states theorem; that is, all molecules of size r obey the se reduced equation of state. Fourth, for a homologous ser of liquids (such as the normal alkanes) the theoretical lling point increases with increasing molecular weight, observed experimentally.

The generalisation of equation (1) that is appririate for a binary mixture is straightforward. Formally, t system is ternary (two types of molecules, of sizes  $r_1$  and  $r_2$  lus holes). The only new parameter that is required to describbe mixture is the interaction energy  $\varepsilon_{12}$  between the two comments. The free energy of mixing,  $\Delta G_m$ , is given by

$$\Delta G_m = \overline{r}N \left(\overline{E}_h \mathbf{G}_{12} - x_l E_h^{1} \mathbf{G}_1 - x_2 E_h^{2} \mathbf{0}\right)$$
 (9)

and

$$G_{12} = -1/v + Pv + T[(v-1)\ln(1-1/v) + (1/r)\ln(1/+ + (x_1/r_1)\ln x_1 + (x_2/r_2)\ln x_2]$$
(10)

where,  $N = N_1 + N_2$ ;  $\bar{r} = (r_1 N_1 + r_2 N_2)/N$ ;  $z = 1 - x_2 = r_1 N_1/\bar{r}N$ ;  $E_h^1 = \gamma \varepsilon_{11}/2$ ;  $E_h^2 = \gamma \varepsilon_{22}/2$ ;  $\bar{E}_h = \gamma/2(x_1^2 \varepsilon_{11} + 2x_1 x_2 \varepsilon_{12} + x_2^2 \varepsilon_{22})$ ;  $T = RT/\bar{E}_h$ ;  $P = Pv_h \bar{E}_h$ ;  $v = V/V_o$ ;  $V_o$  $= \bar{r}Nv_h$ ; and  $G_1$  and  $G_2$  are the free energies or the pure components, 1 and 2 [compare with equatic (1b)]. The enthalpy, entropy, and volume changes that oca on mixing are obtained in the usual way by taking derivates on  $\Delta G_m$ . The functional form of the equation of state of the ixture is the same as that for the pure fluid, except that the reded variables are as in equation (10), and r is replaced by  $\vec{r}$ . Thextension of the theory to any number of components onlyrequires the obvious generalisation of equations (9) and (10) Only in the limit  $\mathbf{v} = \mathbf{v}_1 = \mathbf{v}_2 = 1$  does  $\Delta G_m$  reduce to the Fory-Huggins expression. In the general case of zero volumechange, v =  $x_1v_1+x_2v_2$ , there are still significant contribution of  $v_1$  and  $v_2$ to both the entropy and enthalpy of mixing.

The chemical potential  $\Delta \mu_1$  is given by:

$$\Delta\mu_{1} \equiv (\partial \Delta G_{m}/\partial N_{1})_{P,T,N_{2}} = r_{1}(\bar{E}_{h}G_{12} - E_{h}^{1}G_{1} + x_{2}\partial(\bar{E}_{h}G_{12})/\partial x_{1})$$
(11)

and  $\Delta\mu_2$  can be obtained by symmetry.

For liquid-liquid equilibria, the binodal is letermined by equating chemical potentials across the liquid hases. For a non-polar polymer mixture  $(r_2 \gg r_1)$  where  $\epsilon_1 = (\epsilon_{11}\epsilon_{22})^{1/2}$ both upper and lower critical temperatures of solution are predicted. Theoretical, negative, excess volumes are also obtained under these conditions. Equating chemical potentials across liquid and vapour phases allows for he complete determination of the boiling point composition diagram (distillation diagram). For  $r_1 = r_2 = 1$  and  $\varepsilon_{12} = (\varepsilon_{11}\varepsilon_{22})^{1/2}$ , nearly ideal behaviour is obtained. Deviations o  $\epsilon_{12}$  from the geometric mean, or large dissimilarities in molecular size, cause maxima or minima to occur in these diagrans; azeotropes are thus predicted. To our knowledge, no other molecular theory has been presented which predicts the entire range of distillation phenomena from a unified point of view.

## Load-being structures and crysl intergrowth

As far as 1m aware, no one has attempted to place the concept of cstal-crystal intergrowth on a quantitative basis. The object this note is to calculate the probability of the formation ca three-dimensional load-bearing structure on the basis of ystal-crystal intergrowth.

The originf the load-bearing capacities of structures like inorganic ceents and bone is still disputed. In each of these structures, temselves composites, the solid component, generally asimed to be the main load-bearing element, is mainly crystline in nature, though usually of submicrometre size. Two mehanisms have been proposed to explain load-bearing capaties. In the first it is assumed that the solid particles fon a physically bonded structure<sup>1-3</sup> whereas the other assmes that the solid particles form a three-dimensional structure by crystal-crystal intergrowth at the points of contact<sup>4-7</sup>. I either case, the points of contact or the points of intergrowt must be numerous and spread throughout the volume for to structure to be functional.

In inorgan cements as well as in bone, crystallisation begins in isolated agions. Subsequent crystallisation and crystal growth bringthe crystals from different regions into contact. Thus, when vo crystals from two different regions meet, they do so at a radom orientation. The case of apatite crystals in long bones i somewhat complicated. The apatite crystals in long bones o a newly born baby are randomly oriented; those in mature boe, however, have a preferred orientation with the c axis paralle to the long axis of the bone.

When two crystals from two different regions come into contact two possibilities may arise. In the first case, the atoms at the interfece can be considered to belong to the crystal structures of both crystals and because of the structural continuity the intercrystalline bond is nearly as strong as the intracrystalline bond. In the second case there is no such relationship and the intercrystalline bond is much weaker than the intracrystalline bond so the crytsals can be considered to be physically bonded.

For ideal cystals, crystal-crystal intergrowth can only occur when the crystals meet each other in a symmetry related indistinguishable orientation. For micrometre sized real crystals some angular relaxation of the order of the mosaic spread in a single crystal—that is 3-4°—is expected. The probability that two crystals will meet each other in this orientation, by accident, can be calculated.

Let (hkl) be the crystal plane across which the crystal-crystal intergrowth is going to occur. Let c be an axis normal to the plane having an n degree rotation symmetry and a be an axis in the plane. If a second crystal is brought into contact with the first an intergrowth will occur when both c and a axes of the two crystals are within the angular relaxation zones of each other. Statistically, the second c axis can approach the first from any point on a hemisphere drawn round the first. The probability of two c axes being within the relaxation cones of each other is given by

$$P_c = (1 - \cos 4^\circ) = 0.002$$

The a axis will repeat n times in 360°, so that when two c axes are parallel to each other the probability of the two a axes coming within each other's relaxation zones is given by

$$P_a = n \times 4^\circ/360^\circ = n/90$$

so that the total probability of intergrowth is

$$P_t = P_c P_a = n/45,000$$

The probability of a third crystal joining either of the first two in intergrowth orientation is given by  $P_t^2$  and so on. Thus the probability of the formation of an extended structure on this basis is vanishingly small. Even if most of the c axes are parallel to each other, somewhat like apatite crystals in mature bone, the probability that a load bearing structure will form will still be extremely small. The probability of obtaining an aggregate 1 mm long from micrometre-sized crystals on this basis will be  $(n/90)^{899}$  where n is a small integer. This very low probability is consistent with a scanning electron microscopic work on plaster of Paris blocks. This work did not reveal any definite evidence for the occurrence of extensive crystal-crystal intergrowth though one of the objects of the study was to search for it.

In the case of physical bonding of the crystals there is no requirement of any continuity of atomic arrangement between the participating crystals, so bonding will occur whenever crystals come sufficiently close to each other. The probability of the formation of an extensive structure on this basis depends only on the packing density of the crystals and on their size and shape<sup>10</sup>.

Thus the most probable mechanism of the origin of loadbearing capacities of bone and inorganic cements is the physical bonding of the crystals.

# Direct observation of alkali metal colloids in alkali halide crystals

SIEDENTOPF¹ observed that sodium chloride crystals containing atomically dispersed F centres turned blue and exhibited Tyndall scattering when annealed at 400° C. These effects were attributed to colloidal particles of sodium metal formed in NaCl crystals by aggregation of F centres during the annealing process. Savostianova² applied the Mie³ theory to absorption and scattering of light from colloidal metallic particles suspended in dielectric media and predicted colloid sizes in excess of 80 nm. The blue colour of natural rocksalt, investigated⁴ using optical absorption and photoconductivity, was similarly attributed to colloids. Ionising radiation also produces colloidal absorption bands in irradiated alkali halide crystals under certain conditions⁵-10.

Increasingly sophisticated techniques have been applied to the study of these colloidal centres, for example, ultramicroscopy<sup>11</sup>, diffuse X-ray scattering<sup>12,13</sup>, NMR<sup>14,15</sup>, EPR<sup>16-18</sup>, electrical conductivity<sup>19</sup> and surface replication<sup>20-26</sup>. Despite 70 years of investigation, their existence has still remained controversial, partly for the want of a direct method for observing actual colloidal particles *in situ*, and in part to disagreement over possible mechanisms of colloid formation<sup>27-29</sup>, particularly over the role of existing defects such as dislocations and impurities<sup>11,25,30-32</sup>.

Fig. 1 a, Spherical inclusions preferentially nucleated along dislocation lines in KCl additively coloured with potassium to  $10^{25}$  F m<sup>-3</sup> and annealed for 1 h at 673 K to produce a colloid absorption band. b, Cylindrical inclusions along a dislocation line in KI additively coloured with potassium to  $8 \times 10^{23}$  F m<sup>-3</sup> and annealed for 4 h at 433 K. c, Faceted inclusion in KI additively coloured with potassium, showing weak Moiré fringes normal to the diffraction vector g.

Transmission electron microscopy is a sufficiently direct technique but attempts<sup>5</sup> to observe existing lattice defects in alkali halide crystals using this technique<sup>33</sup> have always been hampered by the catastrophic radiation damage induced by the investigating electron beam. New techniques<sup>24,35</sup> involving electron microscopy at liquid helium temperature can circumvent this problem and allow almost rousine electron microscopy of existing lattice defects; these methods have been applied recently to studies of dislocations in deformed crystals<sup>36</sup> and interstitial stabilisation in irradiated crystals<sup>37</sup>. We have here applied them to the first direct electron microscopical observation of what we believe are alkali metal colloids in additively coloured alkali halide crystals.

Potassium chloride crystals (Harshaw Chemical Company) were additively coloured with potassium vapour, using van

Doorn's method38, to produce an F-centre densityquivalent to a stoichiometric excess of potassium ator between  $2\times10^{24}$  and  $10^{25}\,\mathrm{F}\,\mathrm{m}^{-3}$ . The crystals were section parallel to {100} and {110}, annealed in dry nitrogen vacuum for 1 h at 673 K and either rapidly quenched or fuce-cooled. Optical absorption measurements indicated a largbsorption band peaking between 750 and 850 nm, corronding to average colloid diameters in the range 90-120 nnn the Mie theory. Potassium iodide crystals (Quartz et lice) were similarly coloured to an F-centre density of 8×23 F m<sup>-3</sup>, sectioned and annealed for 4 h at 433 K. Opticabsorption measurements indicated a broad colloid abstion band peaking between 700 and 900 nm. Thin foils we prepared from annealed material using a precision chemi polishing method39 and examined at liquid helium temperare34,36 in a 100-kV electron microscope. Approximately 15 s observation time was available for image recording in KCl undan incident electron beam intensity of ·18 A m<sup>-2</sup> before aggration of interstitial radiation defects impeded observation<sup>17</sup>; approximately 45 s was available in KI at 45 A m<sup>-2</sup>.

We observed images from inclusions (Fig. 1a) which we ascribe to potassium metal colloids. The obserd inclusion dimensions vary between 50 nm and > 400 nmhose of the latter size being of the order of the foil thicknessVhen small, these inclusions are approximately spherical; larr inclusions are often faceted (Fig. 1c). They were observeoy structure factor contrast40,41 appropriate to coherent prepitates with different extinction distances  $\xi_g$  from the matri ( $\xi_{220}$  (KCl) = 87 nm;  $\xi_{220}$  (KI) = 70 nm;  $\xi_{220}$  (K, f.c.c.= 170 nm). Absorption contrast was also observed. The dtribution of inclusions was found to be microscopically inhorgeneous, the average density being of the order 1017 m-3 Independent measurements using a surface replication techniue26 confirm this size distribution, inhomogeneity and morhology. The number of potassium atoms which could be stabised in aggregates of this size and distribution adequately acounts for the measured loss of F centres during anneal.

Absence of any additional diffraction feature in selected area diffraction patterns from regions containin these inclusions suggests that potassium atoms are retained itheir original face-centred cubic (f.c.c.) positions within thealkali halide matrix, with a lattice parameter not too different frm the matrix  $(a_0 \text{ (KCl)} = 0.629 \text{ nm}; a_0 \text{ (KI)} = 0.707 \text{ nm}; a(\text{K, f.c.c.}) =$ 0.655 nm;  $a_0$  (K, b.c.c.) = 0.535 nm at 3001). When the inclusions were sufficiently large, weak Moiréfringes were observed (Fig. 1c) similar to those observed 42 for misfitting coherent precipitates. The fringe spacing is not wil defined, but nevertheless corresponds to a coherency strain<sup>43</sup>magnitude of the order 0.5% in both KCl:K and KI:K. The actal differences in alkali metal and alkali halide lattice parametes correspond to expected coherency strains of 0.31% for KCIK (matrix in compression) and -0.76% for KI:K at 300 K (matrix in tension), using for the bulk modulus of f.c.c. octassium the value (4 GN m<sup>-2</sup>) available for body-centred cubic (b.c.c.) potassium metal. The smallness of the strain values arises from the large compressibility (small bulk modulus) of the alkali metal lattice compared with the stiffness of the alkali halide matrix. Little matrix strain-field contrast44,45 is observed surrounding the larger inclusions as expected from he strain field visibility limits established by Ashby and Brown<sup>44</sup>.

In crystals which were rapidly quenched from the annealing temperature, inclusions were often surrounded by dislocation tangles. When care was taken to cool crystals sowly from the annealing temperature to preserve the existing dislocation structure, inclusions were observed to have preferentially nucleated along existing dislocation lines (Fig 1a and b). In such cases, they were more uniform in size and were regularly spaced along the dislocation lines; their shape vas distorted in the direction of the dislocation line. This observation confirms the special role of dislocations in sensitising the nucleation of colloids. We have so far also made observations on similar inclusions in the systems KBr:K and NaCl:Na.

We graphly acknowledge provision of microscope facilities the Oxford University Department of Metallurgy'd Science of Materials.

#### The aerodynamic diameter of branched chain-like aggregates

AGGREGATES of a large number of submicron primary particles are produced by industry and automobiles. Such aggregates are also used in laboratory studies, so the fluid drag on these aggregates is of considerable interest.

Vomela and Whitby have studied the fluid-drag on chain-like aggregates, produced by an exploding wire as well as by hydrocarbon flames. Their data show a Stoke's diameter (diameter of a sphere having the same bulk density and settling rate as the aggregate) larger than the volume equivalent diameter (diameter of a sphere having the same volume as the aggregate) of an aggregate, which obviously cannot be correct4.

We deal here with aggregates of submicron iron oxide particles, produced by an exploding wire in an aerosol tank. The aerosol is labelled with 59Fe by pre-irradiation of the wire with neutrons. The primary particle size distribution can be varied by varying the specific explosion energy.

Some time after the explosion, when aggregates are formed due to coagulation, the aerosol is sampled and analysed with a centrifugal spectrometer according to Stöber and Flachsbart<sup>2</sup>, which deposits the aerosol particles on a strip according to their aerodynamic diameter (diameter of a unit density sphere having the same settling rate as the aerosol particle), which is characteristic for the fluid drag.

The relationship between the mass and the aerodynamic diameter of the aggregates can be obtained from measurements of the radioactivity and particle number (obtained by counting from optical and for small aggregates from electron microscope pictures) along the deposition strip. The primary particle size distribution is determined using electron microscopy, with negatively stained catalase crystals3 as an internal length standard. It has been shown that the primary particle size distribution can be approximated by a log normal size distribution (characteristic features: the geometric mean diameter  $d_{1s}$ and the geometric standard deviation  $\sigma_s$ ). The number n of primary particles of the aggregate can be calculated from the equation:

$$m = (\pi/6) \rho n d_{1g}^{3} \exp(4.5 \ln^{2} \sigma_{g})$$
 (1)

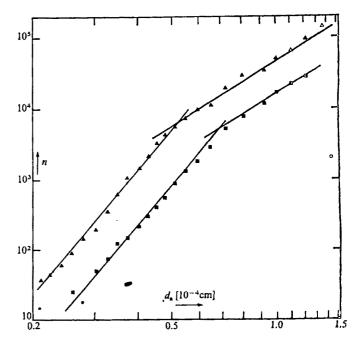

Fig. 1 The relationship between the number (n) of primary particles and the aerodynamic diameter  $(d_a)$  of branched chain-like aggregates of submicron iron oxide particles.  $\blacktriangle$ ,  $d_{1g} = 0.027 \ \mu m$ ,  $\sigma_g = 1.8$ ;  $\blacksquare$ ,  $d_{1g} = 0.041 \ \mu m$ ,  $\sigma_g = 1.8$ .

with: m = mass of the aggregate and  $\rho = \text{density}$  of the aerosol material = 5.24 g cm<sup>-3</sup> for the particles studied by us (aerosol material is Fe<sub>2</sub>O<sub>3</sub> as could be determined by means of X-ray diffraction).

With the aid of equation (1) the relationship between the number of primary particles and the aerodynamic  $d_a$  of the aggregates can be obtained from the measurements of the aerosol mass and number distributions on the deposition strip in the aerosol centrifuge.

Figure 1 shows those experimental results already obtained for two different primary particle size distributions. For  $n \le 5 \times 10^3$ ,  $d_a$  is proportional to  $n^{1/6}$ , whereas for  $n \le 5 \times 10^3$   $d_a$  is proportional to  $n^{1/3}$ .

Figure 2 shows that the configuration of aggregates with less than about  $5 \times 10^3$  primary particles is linear in contrast to

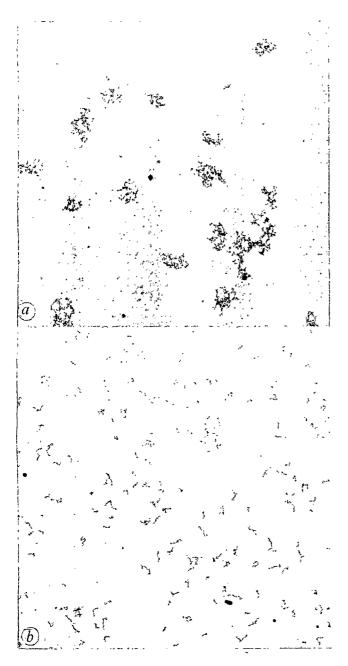

Fig. 2 Electron microscope pictures of branched chain-like aggregates of submicron iron oxide particles ( $d_{1g} = 0.027$ ,  $\sigma_g = 1.8$ ). a,  $d_a = 0.925 \mu m$ ,  $n = 3.10^4 (\times 165)$ ; b,  $d_a = 0.259 \mu m$ ,  $n = 100 (\times 700)$ .

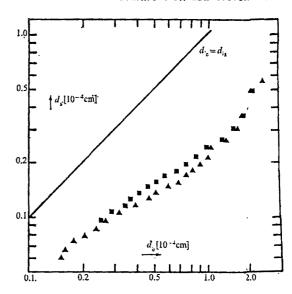

Fig. 3 Relationship between the volume equivalentameter  $(d_e)$  and the Stoke's diameter  $(d_s)$  of branched chain-li aggregates of submicron iron oxide particles.  $\triangle$ ,  $1 d_{1g} = 0.027a$ ,  $\sigma_g = 1.8$ ;  $\blacksquare$ ,  $1 d_{1g} = 0.041 \ \mu m$ ,  $\sigma_g = 1.8$ .

aggregates with more than about  $5 \times 10^3$  prinry particles, which are irregular three-dimensional networks.

In accordance with Stöber<sup>4</sup>, the following relaonship can be derived for the linear aggregates of polydiserse primary particles

$$d_n = k n^{1/6} \sqrt{(\rho/\rho_0)} d_{1s} \exp(2ln^2\sigma_s)$$
 (2)

with k = proportionality constant,  $\rho_0 = 1 \text{ g cn}^{-3}$ .

The values of k resulting from our experiment (k = 0.92 and 0.87 respectively) are somewhat smaller than itöber's result (k = 1.077) for linear aggregates (up to eight prinary particles) of monodisperse polystyrene spheres.

The relationship between the number of primay particles and the aerodynamic diameter of the aggregates with more than  $5 \times 10^3$  primary iron oxide particles, has been found to be

$$d_a = f n^{1/3} \sqrt{(\rho/\rho_0)} d_{1g} \exp(1.5i^2 \sigma_g)$$
 (3)

with: f = 0.903 for cluster aggregates as results from Stöber's study; f = 0.250 for branched chain-like aggregates with more than about  $5 \times 10^3$  primary particles, as results from this study.

The difference between the values of f found an be ascribed to the totally different packing densities of the aggregates studied by Stöber (cluster aggregates of monodsperse polystyrene spheres) and ourselves (fluffy aggregates of ubmicron iron oxide particles).

The relationship between the Stoke's diamete, which can be calculated<sup>4,5</sup> from  $d_a$  and the volume equivalent liameter of the aggregates, is shown in Fig. 3. In contrast to the lata of Vomela and Whitby<sup>1</sup> we found Stoke's diameters of the branched chain-like aggregates smaller than their volume equivalent diameters, which is in agreement with theoretica considerations.

The present results are of great importance, for example, in describing coagulation of solid aerosol particles. Until now the approximation of the droplet model was used in which the particles are assumed to be droplets which unite to form one new droplet. In fact, this implies that the Stcke's diameter of chain-like aggregates equals the volume equivalent diameter. Obviously, this is incorrect.

#### Decline c PCB concentrations in North tlantic surface water

POLYCHLOROPHENYL (PCB) concentrations in North Atlantic surface waterhave declined fortyfold since 1972, following the cessation of ertain industrial uses of those compounds. Industrial sal of PCB for use in products which would allow leakage to thenvironment, for example in plastics, inks and paints were spped in the United States and Sweden during 1970-711; anin 1972-73 other European countries and Japan initiated a sinlar action<sup>2</sup>. In 1971 and 1972 average surface concentration of PCB in the open North Atlantic Ocean were about 30 ng<sup>-1</sup> (ref. 3 and C. E. Olney and J. J. Quinn, unpublished) 3y April of 1973 the concentration in the Sargasso Sea had been educed to 1 ng l-1 (ref. 4); five months later we found that the decline had levelled at 0.8 ng l<sup>-1</sup>, a concentration which was stl present in February 1974 in the north-west Atlantic. The ccumulated data are presented in Table 1. These observations evealing a reduction in surface water concentrations of PCB:ompare well with our February 1974 measurements of a terfold decrease of PCB in the atmosphere over the north-west Alantic since 1973 (ref. 5), and a fivefold decrease

since 1972 in the PCB content of mixed plankton collected along 09°N latitude in September of 1973 (ref. 6).

The data require that about 2×104 tons of PCB were lost from the upper 200 m in less than one year3. To explain this loss, four processes must be seriously considered: (1) apparent dilution of dissolved PCB by vertical and horizontal advection and diffusion; (2) association of PCB with sedimenting particles; (3) evaporative codistillation into the atmosphere and (4) biological and chemical degradation.

The information obtained from the monitoring of bomb fallout radionuclides is relevant to the present problem because like PCB, they are delivered to the ocean from the atmosphere, can exist in dissolved and particulate phases, and experienced a similar decreased input after the nuclear test ban agreements of

† Method C was used.

1963. For example, strontium-90 which is mainly in the dissolved state in seawater, required more than five years after the test ban treaty to decline to one-half the surface water concentrations of 1963 (ref. 7). Thus, depletion of dissolved PCB from the upper ocean by advection and diffusion seems too slow to explain the observed rate. The rate of PCB removal from the surface waters more closely resembles the behaviour of the plutonium nuclides 239-240Pu which are believed to be associated with particulates8. The vertical distribution of plutonium isotopes in the Atlantic was best explained as being associated with particles falling at rates of 70-392 m yr<sup>-1</sup>. The well known affinity of PCB for solid surfaces suggests that adsorption on falling particles could be a major transfer mechanism. In fact, if 2×104 tons or less of PCB has been transferred to the deep ocean each year (1970 was the peak production year) for the past 10-15 yr and was dispersed throughout the entire water column, the concentrations to 3,500 m would still be less than 2 ng l<sup>-1</sup>. Two 1973 profiles of PCB in the water column are presented in Table 2. The profile at 40° 00'W was typical of eight other stations in the North African and Cape Verde Basins; in contrast, the station at 70° 20'W revealing very low PCB levels at the surface, was similar to nine other stations in the North American Basin the same year.

We are, at present, unable to ascertain the relative importance of evaporative codistillation of PCB from the surface water or of biogeochemical degradation. Either process could explain the lower surface water concentrations in the North American Basin. There is, as yet, no evidence of biological metabolism of PCB in the marine environment.

We note the rapid response of the open-ocean mixed layer to the reduction of industrial discharges of PCB. Efforts to determine the mechanism of this efficient transfer process are

#### Origin proposed for non-protein amino acids in meteorites

THE amino acids that have been identified in several meteorites1,2 can be divided into two classes: those present in proteins and those which are not. The presence of the non-protein amino acids, D- and L-β-aminoisobutyric acid and β-alanine, is described as evidence for the indigenous origin of meteorite amino acids and against terrestrial contamination<sup>1</sup>. It is implied that these \beta-amino acids arise by prebiotic condensation of ammonia, methane, hydrogen, water and other simple primordial molecules3. The β-amino acids and other amino acids can arise from simple molecules by Fischer-Tropsch synthesis in the laboratory. Hydrogen, carbon dioxide and ammonia were heated to high temperatures in the presence of natural catalysts expected to be present in the solar nebula4.

In other experiments, thermal synthesis of amino acids occurred in a simulated primitive atmosphere of methane, ammonia and water, followed by acid hydrolysis of the products. β-Alanine was obtained in high yield, relative to other amino acids, and the straight-chain compound, \beta-amino-n-butyric acid<sup>5</sup>. These amino acids were postulated to arise respectively from hydrolysis of β-aminopropionitrile and the nitrile intermediate arising from addition of ammonia to crotononitrile. Evidence for this route was the identification of succinic acid and N-methyl-β-alanine which are likely hydrolysis products of nitrile intermediates. Production of β-aminoisobutyric acid was not reported in these experiments.

β-Aminoisobutyric acid is a rare amino acid with a curious distribution in nature. It has been isolated only from human urine6, iris bulbs7, flatworms8 and edible mussels9. Man is probably the only mammalian species to excrete p-(-)β-aminoisobutyric acid10 though there is chromatographic evidence for its presence in rabbit urine11. Metabolic experiments suggest that the pyrimidine base thymine, from nucleic acid catabolism, is the precursor of β-aminoisobutyric acid in the human<sup>12-14</sup>. Similarly, metabolic production of  $\beta$ -alanine in rat liver is from the pyrimidine uracil<sup>15</sup>.

By analogy with these known reaction sequences catalysed biologically, I suggest that heterocyclic compounds could also act as precursors for the \beta-amino acids found in meteorites. In this case, scission of the ring of heterocyclic compounds formed prebiotically would occur under the catalytic conditions of extremes of temperature and radiation thought to occur in space.

The purines, adenine and guanine, and a substanesembling uracil have been detected in the Orgueil meteoriteXanthine, thymine, uracil and derivatives have also been objed experimentally by mimicking supposed prebiotic condits4.

This chemical route to certain non-protein ino acids described above would presumably give racemicixtures of both stereoisomers, for example, both D-, ant-β-aminoisobutyric acid, as found in meteorites1. It would interesting to know if thymine, dihydrothymine, uracil andated compounds, when heated under supposed prebiotic clitions, did give traces of the β-amino acids.

#### Evidence for downwind flights by host-seeking mosquitoes

THE behaviour of flying insects which make up of airborne chemicals in their search for food, oviposition ites or sexual partners can be separated into two phases, th search flight bringing them into contact with the attractant lume and the approach flight leading them to its source1,2. Thesecond phase is characterised by upwind orientation in reponse to the appropriate chemical stimuli3-6. Mosquitoes anknown to fly upwind as they approach a warm-blooded hos -9. For most insects relatively little is known of the pattern othe preceding search flight which Haskell2 described as 'wandering', but where the wind is light it may be upwind1. Experiments n West Africa have shown that the majority of mosquitoes enteed flight traps from the downwind side, that is they appeared to have been flying upwind, regardless of the presence or absence of a host (ref. 10 and W. F. Snow, unpublished). Iere we report experiments that unexpectedly provide evidence br the opposite type of behaviour.

If the search flight is in a generally upwind direction, it should be possible to divert mosquitoes round ahost by setting up a barrier on the downwind side and so provile a measure of protection from their attacks. The barrier would need to be sufficiently far away for the mosquitoes to encounter it before they detected the presence of the host, so that directed responses towards the host would not be elicited. This distance was estimated by Gillies and Wilkes<sup>11</sup> to be less than 18 m for a host the size of a man. A host stationed at this distance upwind

Teffect of barriers on mosquitoes flying upwind towards a st. Crosses represent hosts protected by, a, semicircular bærs on the downwind side; c, upwind side; and, b, unproted. The thick arrow represents wind direction, and the fine aws the flight paths of mosquitoes. The plume of attractant in the host is shown as an ellipse, swinging in a narrow arc in a variable wind.

of the barrishould, therefore, receive fewer bites than a bait in the open one protected on the upwind side (Fig. 1).

A bait staned downwind of the barrier (Fig. 1 c) might well have in within its wind shadow which could have affected the insity of insects on the leeside regardless of their direction of ght12. So we decided to compare the attack rate on a host upind of a barrier with that on an unprotected bait at the pointmarked X in Fig. 1a and b. A semicircular fence of plastic mquito netting was constructed with the opening perpendiculato the prevailing wind. The fence was 2.9 m high, 57 m long ar formed part of a circle of radius 18.3 m. It was set up in arextensive area of cleared farmland near Sapu, The Gambia0.5-1 km from the nearest village. Two human 'baits' sat 36n apart at points a and b (Fig. 1) and caught the mosquitoes i tubes as they settled to bite, changing places at halftime. Wil speed was measured at a height of 1 m and wind direction wasecorded at 1-2 min intervals. Weather conditions were favourale on eight nights in July 1973, for a total catching time f 6.5 h. On these nights the wind was within 45° of the prevaing direction for 96% of observations. Mean wind speed was 2 ns<sup>-1</sup>. The fence was highly permeable, air flow at a point 3 m do nwind from it being reduced by a factor of 0.62 at ambient winespeeds.

In a seconseries of experiments, the half-circle of fence was converted in a complete circle of the same height. Paired catches by hman bait were done in the same way as before, except that the control bait was 70 m from the nearest part of the fence. Mean wind speed in the open was 0.9 m s<sup>-1</sup>.

The results with the half-circle fence showed that the mean nightly ratio of mosquitoes caught upwind of the fence to those in the open was 0.97. Thus virtually identical numbers were caught by the 'protected' and by the exposed bait (total catch 814 mosquites, 84% being Mansonia (Mansonioides) spp.). On the other hand, the results of 12 paired catches inside and outside the complete circular fence showed that the mean nightly ratio if catches inside to catches in the open was 0.69.

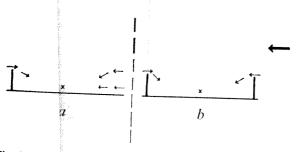

Fig. 2 Section through, a, semicircular fence and, b, circular fence to show possible approach paths of mosquitoes (fine arrows) to the host (X). Wind direction is indicated by the thick arrow on the right.

The difference for catches of Mansonia spp., which totalled 2,048 mosquitoes, was highly significant (P < 0.01). This shows that the circular fence reduced the numbers reaching the bait by something like 30%.

With the half-circle fence mosquitoes could have reached the bait by flying downwind at any level or upwind only over the top of the fence (Fig. 2a). The circular fence would have excluded low-level fliers and only permitted the approach of high-flying insects (Fig. 2b). If the mosquitoes that reached the bait in the first experiment had mainly approached by flying over the fence, the exclusion of low-flying insects in the second experiment would not have had any effect on the catch. As, on the contrary, there was a marked reduction in this catch, we conclude that a significant number of mosquitoes reached the vicinity of the bait in the first experiment by flying at a low level downwind. Their search flight before the detection of host stimuli must therefore have been in a generally downwind direction and low enough for them to encounter the odour plume from a ground level host. Thereupon they presumably turned and tracked back upwind toward the host. This would make for a much more efficient host-seeking strategy since, for a given output of energy, the insect would be able to cover a much larger area than if it were restricted to upwind movements.

#### Diffuse competition in Lepidoptera

THE effects of interspecific competitive encounters have traditionally been viewed in terms of species replacement, but recent workers1.2 have recognised the importance of weak or diffuse competition, which leads only to reduced niche volume. Evidence of such niche restriction has been obtained from the study of bird communities, where it has been shown that species often expand niche dimensions in areas with few species<sup>2,3</sup>. For example, one-third as many bird species are present on the island of Puercos as on the nearby Panamanian mainland and the insular birds forage in a wider range of habitat types than conspecific mainland birds4. Unfortunately this rather direct method of relating changes in niche width to changes in competitive background is often difficult to apply but the importance of competition can be evaluated in other ways. It is generally conceded that if competition occurs at all, it will be strongest among phenotypically similar species.

More explicitly, the intensity of competition which a species faces should be inversely related to its phenotypic isolation, where such isolation is a complex function of the phenotypic distance between a species and coexisting species which share limiting factors.

The relationship between intensity of competition and species abundance is not likely to be a simple one. Much depends on the limiting factors involved in the competition. The abundance of resource-limited species is, on the short run at least, related to the abundance of the resource. The data from Puercos<sup>4</sup> do, however, indicate a flexibility in resource abundance, depending on the utiliser's definition of the resource. The potential overlap of such definitions will clearly lead to competition. In cases where resource limitation is unimportant, the effects of competition on abundance could be equally important, but not necessarily any more clear-cut; few limiting factors are totally nonspecific, yet, equally few are totally specific.

It is difficult to make a general case for the resource limitation of herbivorous insect populations. Certainly, as Hairston, Smith and Slobodkin<sup>6</sup> point out, insects rarely strip their food plants of foliage. In non-resource limited species the possibility of competition arises when several species share mortality factors<sup>7</sup> such as parasites, predators or disease, for a group of species will then tend to be regulated as a whole rather than as individual units.

We decided to analyse patterns of abundance in lepidopterans because large numbers of species are present in a local fauna. Moreover, the families to which these species belong are represented by differing numbers of species. Species which belong to small families will be more phenotypically isolated from the lepidopteran community as a whole than species belonging to families represented by many species and the present study demonstrates that species in these small families tend to have higher population densities.

As it is difficult to sample the abundance of an entire lepidopteran community in any meaningful way, this study has been restricted to an analysis of the abundance of night flying moths. To reduce the size variation of the species considered and to avoid taxonomic difficulties, Microlepidoptera were

Table 1 Family differences in species abundance

One 'sample' is a collection from one light over one season.
\*Perth Road, Frontenac Co., Ontario (1970-1971); four samples, total no. of individuals = 66,484.

†Chaffeys Locks, Leeds Co., Ontario (1969-1970); four samples, total no. of individuals = 18,146.

excluded from study. Collections were carried out at two sites approximately 10 miles apart. Site 1 was situated in a large area of undisturbed deciduous forest, while site 2 was situated in an area which had been subject to limited clearing. Moths were collected with a 20 W ultraviolet light set against a white cloth background. Trapping periods have been listed elsewhere<sup>8</sup>, but generally extended from May until mid September.

Fifteen families of moths were represented in the collections. At site 1, 401 species of Noctuidae, 168 species of Geometridae, 43 species of Notodontidae, 34 species of Arctiidae and 22 species of Sphingidae were collected. Ten additional families (Citheroniidae, Drepaniidae, Epiplemidae, Euchromiidae, Lasiocampiidae, Lymantriidae, Nolidae, Saturniidae, Thyatiridae and Zanolidae) were represented by from one to seven species.

Approximately the same number of species per iily were obtained at site 2 although only 307 Noctuidand 140 Geometridae were collected.

Large differences in family abundances as mead by the arithmetic mean number of individuals per ties were observed (Table 1). The Noctuidae were represed at both sites by the lowest average number of individuals species, while the Geometridae were next rarest. Species onging to the three intermediate-sized families were represented average by twice as many individuals as the noctuid spec while the species belonging to the smaller families wertill more abundant. Abundance values based on arithmeticans have the disadvantage that a single extremely commopecies can influence strongly the result obtained. To rule out importance of this effect in our results, the abundance of eacpecies was

**Table 2** Family differences in species abunce, based on mean log, abundance

	Si	te I	Si2			
	No. of species	Mean abundance	No. of species	Mean ibundance		
Noctuidae	401	4.12	307	3.00		
Geometridae	168	4.56	140	3.51		
Notodontidae	43	5.86	43	4.68		
Arctiidae	34	5.65	28	4.46		
Sphingidae	22	5.35	21	4.21		
Other families	32	6.16	32	4.53		

converted to a log<sub>2</sub> scale and placed in a discreabundance class or octave<sup>9</sup>; family abundance was based 1 the mean log<sub>2</sub> abundance of the species in the family. Half the species represented by just a single specimen were thus nitted from the calculations, as they belong to an incompe frequency class<sup>9,10</sup>. This omission leads to anomalous high mean abundance values in families with many species presented by single individuals, an effect which reduced the abundance differences between families in the present dat In spite of this, the same trend in family abundance was obseed (Table 2). The Geometridae were consistently more abunint than the Noctuidae, the Notodontidae, Sphingidae and actiidae were roughly 1.5 times as abundant as the Noctuie, while the other families averaged the highest abundance call.

Family differences in light trap abundance cod result from differences in phototropicity. It is difficult to sugst, however, why an orderly relationship should exist betwee the number of species in a family and the phototropicity f the species included in it. On the other hand, a relationship tween species number and 'real world' abundance is expected competitive interactions are important. Additional evidence ( competition among lepidopterans has been obtained by nalysing the effects of environmental disturbance on spec's abundance and by studying the relationship between the nurber of species in a habitat and species abundance (P.D.N.H. P.S.W., and R.H., unpublished). It seems justified to concude that the family differences in light trap abundance oberved in the present study reflect real world differences in aundance and that these differences are due to competitive interctions among species. The mechanisms by which competitio is mediated are not clear, although shared mortality facors must be important. Certainly, competition of this sort ould be intensified at the family level. A bird searching for the stick-like larva of one geometrid species might well be nore likely to discover the larva of another geometrid spcies than the bizarrely-shaped leaf-mimicking larva of a notodontid; Similarly it is known that many lepidopteran parasites are not species-specific but attack an array of related pecies11.

Our results conflict with the view that insect inpulations 12-14 are regulated largely by density-independent actors, a view which has been based on the results of case history studies of single, necessarily abundant, species. As our study suggests that the common species in a community are often phenotypically isolated from competitors, it is not surprising that

their studys resulted in a misleading impression of the importance species interactions.

#### In vitro hagocytosis of bacteria y insect blood cells

PHAGOCYTOS is an important component of vertebrate cellular immnity and involves several stages which have been described indetail previously1.2. In contrast, little is known about this pocess in insects even though recent work3,4, on intracellular killing of bacteria indicates that phagocytosis probably plas an important role in the defence reactions of insects. In vrtebrates, the development of in vitro techniques has greatly acilitated studies on phagocytosis, but in insects such techniques are not generally available for studying the blood cells (aemocytes) in strictly controlled conditions. Here we describe or the first time the stages in the phagocytosis of

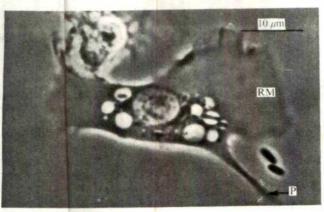

Fig. 1 Plasmatocyte with intracellular E. coli surrounded by large phagocytic vacuoles. Cell shows characteristic cell spreading, ruffled membranes (RM) and protoplasmic extension (P). Haemocyte:bacteria ratio 1:70; incubation time 30 min; phase-contrast optics.

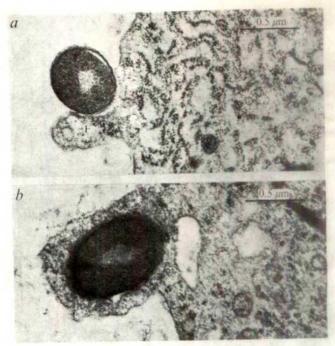

Fig. 2 Stages in attachment and ingestion of E. coli. a, Attachment of E. coli to plasmatocyte cell membrane. Note small filopodial extension (F). b, Plasmatocyte with ingested bacterium projecting from cell surface. Cells fixed in 2:1 (v/v), ice-cold 1% osmium tetroxide and 2.5% glutaraldehyde, postfixed in 0.25% uranyl acetate<sup>6</sup>. Haemocyte:bacteria ratio 1:80; incubation time 45 min.

bacteria by insect haemocytes, using a newly developed culture technique.

Final instar larvae of Galleria mellonella (120-180 mg), were bled by severing a proleg and collecting the haemolymph into Grace's insect medium (Grand Island Biological Company) to give a final haemocyte concentration of 2-3×105 ml-1. All procedures were carried out in a nitrogen atmosphere to delay the toxic effects of haemolymph melanisation. Escherichia coli K 12 (NCTC 10538), were used as test particles in bacteria: haemocyte ratios of 20-100: 1. Droplets (0.2 ml), containing haemocytes and bacteria were suspended in silicone oil in multi-dish trays (6 × 3.5 cm diameter wells; Flow Laboratories) and incubated at 26° C on an orbital shaker (45 r.p.m.) for 10-90 min. For light microscopy, the haemocytes were allowed to attach to glass coverslips after incubation, and the resulting monolayer examined unfixed.

Using previously defined criteria5, five cell types were identified in the haemolymph of G. mellonella; prohaemocytes, plasmatocytes, granular cells, spherule cells and oenocytoids but only the plasmatocytes and granular cells phagocytosed the bacteria. The plasmatocytes were easily identified by their extensive spreading on the coverslips to reveal intracellular details (Fig. 1), and had a much greater phagocytic ability than the granular cells, many of which underwent progressive degeneration in vitro.

The electron micrographs show that the characteristic attachment and ingestion phases of the phagocytic process in vertebrates2, also occurred in G. mellonella haemocytes. Initially many of the bacteria became closely attached to the haemocyte surface (Figs 2a and 3a), and the cell reacted by forming fine pseudopods (filopodia), which extended over the bacterial surface (Fig. 2a). The tips of the filopodia eventually fused with each other, or with the haemocyte surface to enclose the bacteria completely in pockets of cytoplasm (Fig. 2b). In this type of ingestion no well defined phagocytic vacuoles were formed and the bacteria frequently appeared, in low power electron micrographs, to lie directly in the cytoplasm (Fig. 3a). This 'close contact' process explains previous light microscopy reports of engulfed particles lying in the haemocyte cytoplasm

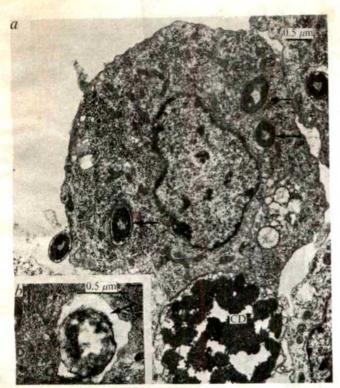

Fig. 3 Intracellular bacteria. a, Plasmatocyte with three ingested E. coli (arrows). Note lack of phagocytic vacuoles, and uptake of cell debris (CD) by invagination of cell membrane. b, Bacterium within well defined phagocytic vacuole (arrow). Fixation and incubation as in Fig. 2.

without vacuole formation7. Sometimes however, ingestion occurred by the formation of phagocytic vacuoles (Fig. 3b) similar to those described previously in infected haemocytes8. In the light microscope, these vacuoles often appeared enlarged, probably as a result of the high degree of cell spreading in the monolayers (Fig. 1).

These results confirm previous descriptions of particulate ingestion by insect phagocytes8-10 and show that bacterial phagocytosis can occur by pseudopod formation alone. The uptake of larger particles, however, such as cell debris is probably accomplished by invagination of the cell membrane (Fig. 3a) to form intracellular vacuoles.

Finally, although lysosomes are known to occur in insect haemocytes11,12, such bodies were not apparent in G. mellonella plasmatocytes. If phagocytosed bacteria are killed and degraded in the haemocytes, then the origin of the enzymes involved is unknown. We are at present utilising this in vitro technique to investigate this problem, together with other aspects of insect cellular defence reactions.

We are grateful to Professor E. W. Knight-Jones in whose department this study was carried out, and to the Royal Society and the Science Research Council for financial assistance to N.A.R. and a studentship to A.F.R.

#### Giemsa banding of metaphase chromosomes in triatomine bugs

Considerable progress has been made in developithe formal genetics and cytogenetics of several insect vectors disease1,2, notably with mosquitoes, houseflies and tsetse flies which the polytene chromosomes provide suitable materiabr detailed analysis of chromosome morphology. The trianine bugs (Hemiptera, Reduviidae) are medically important vectors of Chagas' disease in the Americas, yet cytogenetic immation on these insects is meagre<sup>3-8</sup>. These bugs present the se problems which, until recently, limited developments imammalian cytology in that they possess a large number (typidy 2n = 22) of small, almost indistinguishable chromosom. Further, since their chromosomes are also holokinetic9 (thas with nonlocalised centromeres) they do not show any imary constrictions and it is correspondingly difficult to regnise arms of a chromosome which are readily seen in chrosomes of organisms possessing discrete centromeres. This ficulty with triatomine material has now been overcome bypplying the Giemsa staining methods, which have been effective developed by mammalian cytologists10-13, to embryonic cellsf bugs with metaphase configurations. The technique I describbere makes possible the identification of individual chromomes within the complements of different species of triatominoug.

The procedure is as follows: 5-7-d-old embryosre dissected out from bug eggs, placed in hypotonic sodium ciate solution (1% for 8 min) and the cells dispersed in 0.25, trypsin in

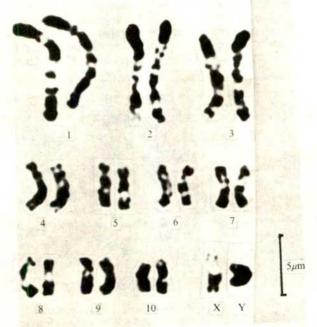

Fig. 1 Metaphase neuroblast from a Triatoma infestans male embryo 6 d old (20 + XY).

0.02% ver. The suspension is washed in insect ringer, centrifuged fixed in alcohol-acetic acid. Slides are prepared by air dryin the normal way14. Dry slides are kept for 1 week at 20° C bre heating at 60° C for 1 h in 2 × SSC (0.3 M sodium chde; 0.03 M trisodium citrate). After rinsing in absolute et ol, preparations are stained in 2% Giemsa (Gurrs 'improved'56) at pH 6.8 for 30 min, dried and mounted. This ASG (acetaline-Giemsa) technique10 has proved to be a more relialmethod for the production of G bands in bug chromoson than other methods which have also proved effective winammalian cells.

Figure hows banding and differentiation of metaphase chromoson in Triatoma infestans, and indicates the results obtainable h this technique. Similar preparations have been obtained fother Triatoma species and also Rhodnius prolixus. Preliminaryalyses indicate that there are prospects for production of romosome maps of triatomine species which could be dvalue in further investigations of chromosome markers artheir application to problems in genetic characterisation a manipulation in the vectors of Chagas' disease.

I thank C. Page for assistance, H. M. Marashi and C. Constanou for supplying material, Professor D. S. Bertram for his engragement, and a grant from the Ministry of Overseas Delopment.

## Forced association between higher plant and bacterial cells in vitro

Symbiotic associations with microorganisms enable many plant species to utilise molecular nitrogen<sup>1-3</sup>. In vitro systems have been developed to study some of these natural associations<sup>4-7</sup>, and here we have attempted to define an experimental system for investigiting the possibility of extending the nitrogenfixing symbosis to additional crop species. We used tissue culture techniques to force an association between the freeliving nitrogen-fixing bacterium, Azotobacter vinelandii and cells of a carrot, Daucus carota cv. Danver's Half Long. The resulting composite callus proliferates slowly on a defined synthetic medium lacking combined nitrogen. In these conditions carrot cells which have not formed an association with Azotobacter are unable to survive.

To form the Azotobacter plant cell association, carrot cell suspensions growing logarithmically in a liquid medium<sup>8</sup>

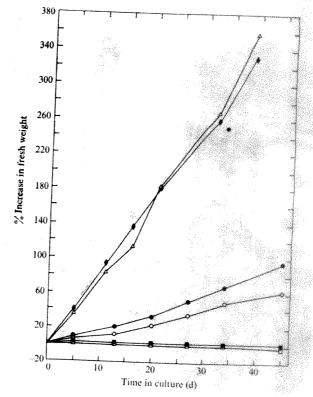

Fig. 1 Growth of Azotobacter-infected and uninfected control carrot tissues on media containing different levels of combined nitrogen. Carrot cells were grown on a Linsmaier and Skoog medium, supplemented with 4% sucrose and containing 3 mg l<sup>-1</sup> indoleacetic acid and 3 mg l<sup>-5</sup> (γ, γ-dimethylallylamino)-purine (2iP). Media were solidified with 1% agar. NH<sub>4</sub>NO<sub>3</sub> and KNO<sub>3</sub> were omitted from N-free medium. Medium which lacked NH<sub>4</sub>NO<sub>3</sub> and contained 0.19 g l<sup>-1</sup> KNO<sub>3</sub> is referred to as low N medium. The adenine autotrophic stepin of feathers. medium. The adenine-auxotrophic strain of Azotobacter vine-landii (ATCC 25308) was grown on modified Burke's nitrogenfree medium (pH 7.8) comprising Na<sub>2</sub>HPO<sub>4</sub> (0.189 g), KH<sub>2</sub>PO<sub>4</sub> (0.011 g), MgSO<sub>4</sub>.7H<sub>2</sub>O (0.20 g), FeSO<sub>4</sub>.7H<sub>2</sub>O (6.0 mg), NaMoO<sub>4</sub> (0.01 g), MgSO<sub>4</sub>, H<sub>2</sub>O (0.20 g), SrCl<sub>2</sub>, 6H<sub>2</sub>O (10 mg), NaCl (10 g), HaHCO<sub>3</sub> (50 mg), adenine HCl (20 mg) and NaCl (10 g), HaHCO<sub>3</sub> (50 mg), adenine HCl (20 mg) and sucrose (20 g) per l H<sub>2</sub>O. All calluses were grown on low N medium for 3 weeks before being transferred to the medium indicated. Initial inoculum weight was approximately 50 mg. Control carrot tissue transferred to N-free ([]), low N (18) or standard Linsmaier and Skoog ((A)) medium. Azotobacter-containing carrot tissue transferred to N-free (()), low N (1), or standard Linsmaier and Skoog (\*) medium.

containing standard nitrogen levels were inoculated with cells of an adenine-requiring strain of A, vinelandii to a final concentration of 106 ml<sup>-1</sup> bacterial cells. After 12 d the mixed cultures were washed and suspended in N-free carrot medium. The cultures were incubated for an additional 2 weeks after which they were plated in N-free carrot medium solidified with 1% Noble agar. The plates were incubated at 23° Coin a 16 h light/8 h dark cycle. The rare and slowly growing colonies were selected as they appeared 3-6 months after plating and were transferred to either N-free or low N medium. The rate of colony formation on N-free medium was approximately 10-4 to 10-5 of the total number of carrot cells plated. Control experiments in which carrot cultures were not inoculated with Azotobacter produced no colonies on N-free medium. Several independent lines of evidence demonstrate that the infected plant cultures depend upon Azotobacter for growth in the absence of combined nitrogen.

• Carrot cells are unable to survive in vitro in the absence of combined nitrogen (Fig. 1). When 1.9 mM KNO<sub>3</sub> is supplied as the sole source of combined nitrogen carrot cells do not proliferate over a 4 month period. On these media calluses which have been recovered after inoculation with Azotobacter cells increase in fresh weight. On medium containing normal

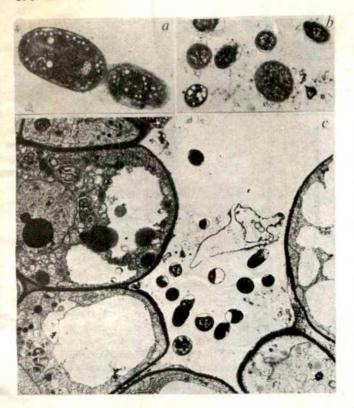

Fig. 2 Electron micrographs showing, a, the fine structure of the bacteria in the composite callus (×13,036); b, bacterial cells in the agar underlying the composite callus (×2,743); c, composite callus growing on low N medium (×2,305). Fixation of callus cultures growing on low N medium for electron microscopy was accomplished by flooding the agar plates with a 3% buffered solution of glutaraldehyde for 4 h, followed by a 6% solution of glutaraldehyde. After 4 d samples were excised from the calius and the underlying agar, washed, and postfixed in a 2% solution of OsO<sub>4</sub> overnight. The fixing solutions and wash were buffered with 0.05 M sodium cacodylate at pH 6.8. The samples were dehydrated in a graded series of acetone solutions at 0–2° C., and embedded in an epoxy resin. Thin sections were stained with uranyl and lead salts before viewing in the electron microscope.

levels of NH<sub>4</sub>NO<sub>3</sub> and KNO<sub>3</sub> (20.6 mM and 18.8 mM, respectively) no difference in growth rates is observed between uninoculated calluses and inoculated calluses which are capable of growth on N-free medium. Inoculated calluses have been cultured for over 18 months and have maintained the ability to grow in the absence of combined nitrogen during that period.

The addition of penicillin G to the medium at a concentration which is known to kill *Azotobacter* cells (50.0 µg ml<sup>-1</sup>) destroys the ability of the inoculated callus to grow on N-free medium. Growth of either inoculated or uninoculated calluses on medium containing normal levels of combined nitrogen is not inhibited by the addition of penicillin. These observations indicate that the ability of the inoculated callus to grow on N-free medium is dependent on the presence of functional bacterial cells in the callus mass.

Composite calluses capable of growth on N-free or low N medium and control calluses were suspended in T broth and in Burke's minimal and adenine-supplemented media. After several days turbidity developed only in the adenine-supplemented Burke's medium. This suspension was plated and identified as the original Azotobacter adenine auxotroph with which the calluses had been inoculated. None of these three media became turbid when inoculated with control carrot callus. The absence of growth in T Broth (which supports growth of a prototrophic Azotobacter strain, but not of the adenine-requiring strain) after a 3 week period indicates that the calluses contain no contaminating microorganisms.

Electron micrographs of inoculated carrot callus grown on low N medium clearly establish the presence of bacterial

Table 1 Acetylene-reduction activity

	Incubation period (h)	$nmolC_2H_4$ pegas $\pm$ s.d.

Azotobacter	1	1.46 6
Carrot callus	10	0.26 0
Carrot-Azotobacter callus	0	0.25 1
Carrot-Azotobacter callus	10	0.71 )7

Approximately 50 mg fresh tissue was placed in 1 nals which were then injected with 0.10 ml acetylene. The Azotobr controls contained approximately  $8 \times 10^7$  cells in 0.10 ml mod Burke's medium. Reactions were stopped by the addition of ml 0.1 N H<sub>2</sub>SO<sub>4</sub>. The ethylene content of samples was determine published gas chromatographic procedures<sup>11</sup>. The composite ca does not evolve ethylene in the absence of acetylene. It is presid that the level of ethylene found in the absence of tissue wassent as a contaminant in the acetylene used in the a/.

cells in the intercellular regions of the tissue (Fig. 2nd in the underlying agar (Fig. 2b). Live bacteria were robserved within the carrot cells. The fine structure of the baca growing with the callus cultures (Fig. 2a) was comparable in essential details to Azotobacter vinelandii<sup>9,10</sup>. No other orgisms were found with the callus or in the agar.

Azotobacter-containing carrot tissue capable growth on N-free medium evolves significantly more ethne in the acetylene assay for nitrogenase than does an inoculated control callus (Table 1).

The association between cells of carrot and Azlbacter has been accomplished by establishing conditions mutual dependency in culture. Presumably, carrot cells reve reduced nitrogen from Azotobacter cells which, in turn, pend upon the carrot cells to satisfy their auxotrophic requement for adenine. This association is not completely stable casionally the callus segregates some cell masses which he lost the ability to grow on N-free medium while others retathis ability. Other calluses become overgrown by bacterialells. Most of the composite calluses (>90%), however, havmaintained a stable association over the 18 months they we been in culture.

An assessment of the usefulness of the carroidzotobacter association and of the magnitude of its effectmust await regeneration of plants from the composite callus and determination if the association is maintained in who plants. Up to now we have been unable to accomplish plantegeneration from these calluses.

The use of genetic markers and nutritional regirements to establish complementary associations between ifferent cell types should be a versatile procedure applicable to diverse experimental situations. The cellular associatin reported in this work might serve as a first step in the deslopment of new or more general symbiotic relationships.

#### Chromatin attachment to nuclear membrane of wheat pollen mother cells

THE cellular mechanisms through which homologues recognise each other before meiosis are unresolved. The problem is compounded in a polyploid species like Triticum aestivum which contains three diploid sets of genetically similar chromosomes1. At meiosis, pairing normally takes place only between the fully homologous partners of a set, so that in spite of their close genetic similarity, homeologues do not synapse. The absence of homœologous pairing depends principally upon the presence of chromosome 5B (ref. 2) and probably derives from the operation of the Ph locus which is distally located on the long arm of that chromosome3.4.

Recently there has been increased interest in premeiotic development in wheat<sup>5</sup> and it has become clear that activities occurring during premeiotic interphase are critical to chromosome alignment<sup>6,7</sup>. As such alignment might be effected by a structural mechanism we undertook a preliminary investigation of the ultrastructure of the wheat pollen mother cells (PMCs) at premeiotic interphase. Here we report our observation of fibrous material which seems to link chromatin to the nuclear membrane during premeiotic interphase, and discuss the possible significance of this material.

Plants of T. aestivum (var. Chinese Spring) were transferred to a constant environment at 20° C with continuous light, about 2 weeks before meiosis in leading tillers. When tillers reached therequired developmental stage they were excised and transferred to the laboratory. The three anthers were quickly excised from each of several florets. One anther from each floret was fixed in 1:3 acetic acid and a Feulgen stained squash preparation prepared. Appropriate florets were identified from cytological examination of these squashes using the criteria previously described5. The remaining two anthers from such florets were fixed in 5% glutaraldehyde and prepared for ultrastructural studies. As the three anthers within a floret are approximately synchronous in development8, those used for ultrastructural studies should contain PMCs at the same stage as the Feulgen-stained samples. Nevertheless, to rule out possible mistakes due to variation between anthers, the stage of development was rechecked using thick and thin sections stained with methyene blue and osmium, respectively. The checks in squashed and sectioned preparations were based on the same criteria. A description of the sequence and appearance of the stages examined has been given previously5.

A distinct and novel feature of the ultrastructure of premeiotic cells was the presence of bundles of fibrillar material in the PMC nuclei Individual fibres had a diameter of about 200 Å. Such fibrillar material was observed adjacent to the nuclear membrane apparently forming attachments at intervals between the membrane and chromatin masses (Fig. 1a and b). Bundles of fibrillar material were also found well within the nucleus. Figure 1d shows one such bundle about 1.2 µm long

and 0.2 µm wide apparently attached to chromatin at one end. Similar fibrillar material was not found in any other anther cells even though it was a general and constant characteristic of the PMCs. The exclusive presence of these fibres in the premeiotic but not in the adjacent somatic cells makes it likely that they are exercising some specific meiotic function.

The order of appearance of these fibrils relative to that of other meiotic nuclear structures is particularly relevant to speculation about their function. The relationship is illustrated diagrammatically in Fig. 2. The fibrils appear in the nuclei of premeiotic cells well before the appearance of any lateral elements and also before the investiture of the cells with callose, another distinctive characteristic of plant meiocytes. The presence of the fibrils overlaps the appearance of lateral elements and of the synaptinemal complex. The fibrils do not persist over the life time of the synaptinemal complexes. They were absent from sections of PMCs that had developed beyond 'stage 3'. At, or soon after 'stage 3', paracrystalline bodies were seen adjacent to the nuclear membrane (Fig. 1e). These may represent a step in the reorganisation or in the degradation of fibrillar material.

Some details of the changes occurring within the neighbourhood of the nuclear membrane are of interest in connection with the relationship of the nuclear membrane to chromosome synapsis, a relationship for which circumstantial evidence is available in a variety of studies8-10. Before and during 'stage 1' a large proportion of the nuclear membrane was in contact with

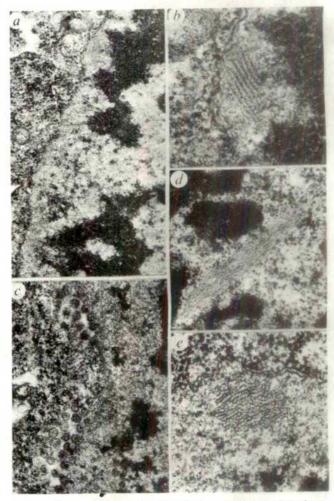

Fig. 1 Electron micrographs of PMCs from Chinese Spring wheat showing: a, fibrillar material located between the nuclear membrane and chromatin masses (× 28,700) at 'stage 215; membrane and chromatin masses (× 28,700) at 'stage 2's, b, a higher magnification (× 71,820) of fibrillar material from a; c, pores in the nuclear membrane at 'stage 2' (× 28,700); d, a large mass of fibrillar material located within the nucleus but away from the nuclear membrane ( $\times$  33,600) and,  $\varepsilon$ , a paracrystalline body adjacent to the nuclear membrane at 'stage 3' (× 57,400).

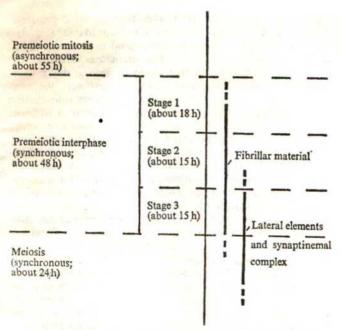

Fig. 2 The time and sequence of appearance of fibrillar material, lateral elements, and SC during premeiotic interphase and meiosis in PMCs of Chinese Spring wheat grown at 20° C.

chromatin either directly or through the fibrous material. Throughout this period the nuclear membrane had very few obvious pores. Early in 'stage 2' it became punctured by numerous pores (Fig. 1c) without, however, removing the fibrous material. Also, during 'stage 2' a zone about 2,000 Å wide containing little or no chromatin appeared next to the nuclear membrane (Fig. 1a and c). This zone, which differed in appearance from the rest of the nucleoplasm, extended around the whole circumference of the nucleus and contained in addition to the fibrillar material numerous structures, less defined but nevertheless sufficiently similar to suggest their functioning as agents of interaction between the nuclear membrane and chromatin.

The discovery of synaptinemal complexes revealed the nature of the mechanism that apparently stabilises meiotic chromosome pairing. The means by which homologues are suitably juxtapositioned before synaptinemal complex formation remain unknown, however. Some organisational framework would seem to be necessary for facilitating the prealignment of chromosomes for synapsis. We have found bundles of fibrillar material apparently forming long range connections with chromatin (Fig. 1d) and also linking chromatin to the nuclear membrane (Fig. 1c). It is noteworthy that the appearance of fibrillar material coincides with the interval when chromosome synapsis in wheat is sensitive to the action of colchicines or to low temperature7. Equally noteworthy is the fact that this interval begins before the initiation of synapsis and of lateral element, or synaptinemal complex formation. Colchicine has been shown to interfere with the normal functioning of the nuclear membrane during meiotic prophase in Lilium8 and, therefore, it may be significant that an appreciable fraction of the fibrils in wheat has been found associated with the nuclear membrane. We suggest, therefore, that the fibrillar material found only in PMCs at stages 1 to 3 may function in establishing or maintaining the spatial coorientation of chromosomes which is a prerequisite for normal meiotic pairing in wheat, and also that it may contain colchicine sensitive protein.

The appearance of fibrillar material before the first synaptinemal complex formation, and its disappearance soon after, would fit this hypothesis. If fibrillar material is responsible for long range links it would presumably cease to be useful once stable links are established between homologues unless the fibrils themselves become incorporated in the synaptinemal complex.

#### Does the rete ovarii act as a trigger for the onset of meiosis?

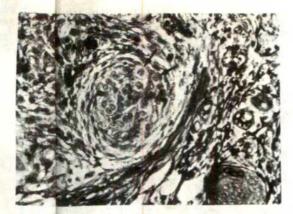

ALTHOUGH transformation of oogonia to ooytes in the mammalian ovary and the subsequent formation of follicles have been much studied the factors which initiate meiosis remain obscure and the control of the formation of the granulosa layer is poorly understood.

Experimental results presented here indicate hat the rete tubuli is important for the onset of meiosis and hat the early formation of the granulosa layer is dependent on the attachment of the rete system to the ovary. Moreover, normal growth or maintenance of the ovarian tissue itself seem to le dependent on the extraovarian rete tubules.

The morphological similarity between the rete carii and the rete testis was already recognised in the last century1. Both consist of tubules lined with cuboidal or cylindrial epithelial cells, which arise from the mesonephros. Duringearly follicle formation a continuity between the tubes from tle rete ovarii

Intact foetal mouse ovary (12 d post :oitum) after inoculation in nude mouse for 14 d. Four apparently normal growing oocytes are seen (× 423) (Stain: Azan).

and the folles has been seen2-6. Kölliker2 and Byskov and Lintern-Moe proposed that cells of the rete ovarii contributed to ficle formation.

To test perimentally whether the onset of meiosis is dependent othe rete ovarii, we used ovaries from two groups of mouse emyos. As the transformation of oogonia to oocytes occurs in thmouse between the 13th and the 17th day of embryonic lil.8, one group was aged 12 d post coitum, in which the rete tube had not yet invaded the gonads, but were lying entirely outse the ovary as extraovarian rete and the meiotic prophase hanot started; in the second group, aged 15 d post coitum, the te was present within as well as outside the ovaries and le major part of the germ cells had entered the meiotic propase. Under a dissecting microscope three ovaries in each grou of six were divided into a cranial part with the adherent extlovarian rete tubules and mesonephric remnants and a caudalart of 'pure' gonadal tissue, without extraovarian rete tubules. The three other ovaries in each group were left intact. In oler to study the transformation of oogonia to oocytes in goads with and without the presence of the extraovarian retetubules the intact ovaries and the cranial and

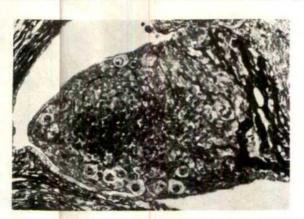

Fig. 3 Caulal part of a 15-d-old mouse ovary without the rete tubules afte 11 d implantation in nude mouse. Some oocytes are seen in the periphery of the graft. No follicles have formed. Necrotic changes are seen in the centre of the graft. (× 423) (Stain: Azan).

caudal parts of ovaries were inoculated subcutaneously into adult female mutant nude mice with aplasia of the thymus (strain BALE/c Nu/Nu). This method of grafting has already

The embryonic ovarian tissue was removed from the nude mice and prepared for histological study after 14 and 11 d respectively. At removal the grafted gonads corresponded to a 5-d-old mouse ovary.

Intact grafted ovaries and the cranial part of the ovary with

the rete tubules attached, both taken from 12-d-old foetuses, contained small and medium sized follicles at 'day 5' (Fig. 1). Their oocytes were indistinguishable from oocytes seen in a normal 5-d-old mouse ovary. The granulosa layer of the follicles was more irregular than normally seen at day 5 with many finger-like extensions to other follicles or to the rete system. Necrotic changes did not occur in these transplants.

The caudal part of the 12-d-old embryonic ovaries without the extraovarian rete tubules grafted for 14 d contained only oogonia (Fig. 2). Oocytes and follicles were never seen. The oogonia were surrounded by undifferentiated fibroblast-like cells. In two of the three grafts necrotic changes were observed. In contrast to this the cranial part of the ovary with the extraovarian rete tubules attached contained oocytes as well as follicles after inoculation for 14 d.

All the ovaries grafted from the 15-d-old embryos, both with and without the extraovarian rete tubuli attached, contained oocytes after implantation for 11 d. Intact ovaries as well as the cranial part of ovarics developed follicles, which corresponded in size to those found in a 5-d-old mouse. None of those grafts showed necrotic changes. The caudal part of the ovary without the rete tubules consisted only of a mass of undifferentiated cells with oocytes lying closely together in group at the periphery (Fig. 3). Also in these rete-depleted grafts necrotic changes were seen in two cases. No follicular formation had occurred.

Recent ultrastructural studies show that the extraovarian rete cells are very active holocrine secreters. Whether the effect of the rete system depends on direct cellular contact with the germ cells or on a trigger component secreted from the rete cells remains still uncertain.

Preliminary studies of implantation of ovaries from rabbits and hamsters support our results. The rete ovarii is essential for the start and maintenance of meiosis and for further ovarian development.

I thank Mrs Inga Larsen, Mrs Anne Lise Mohr, Mrs Gurli Rasmussen and Mr Poul Riel for technical assistance.

#### How selective is high affinity uptake of GABA into inhibitory nerve terminals?

It is now well established that brain slices and homogenates possess distinct high affinity uptake systems for all the major transmitter candidates or their immediate precursor molecules1,2, In the case of GABA and glycine the application of electron microscopic autoradiography to such in vitro preparations has revealed discrete populations of nerve terminals as the major site of amino acid uptake3. In brain slices or homogenates, however, nothing is known about the functional or

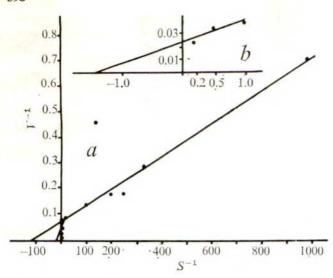

Fig. 1 Lineweaver Burk plots from a single experiment to show high and low affinity uptake of  ${}^{3}\text{H-GABA}$  into cerebellar glomerulus particles. The kinetics of the uptake were characterised by two straight lines, the shallower of which described a high affinity system with an apparent  $K_{\rm m}$  and  $V_{\rm max}$  of 9.6  $\mu$ m and 15.6 nmol per mg protein per 10 min respectively and the steeper (a, shown in more detail above) a low affinity system with a  $K_{\rm m}$  and  $V_{\rm max}$  of 780  $\mu$ M and 46.2 nmol per mg protein per 10 min (S= GABA concentration in nM and V= velocity in nmol per mg protein per 10 min). The glomerulus particles (320  $\mu$ g protein) were incubated at 37° C for 10 min in 1 ml of an isotonic salt medium, buffered with Tris-HCl, pH 7.4 and containing 32 mM of glucose and 10  $\mu$ M amino-oxyacetic acid. The size of the inulin space and  ${}^{3}\text{H-GABA}$  concentration of the particles was estimated by the method of Levi and Raiteri ${}^{13}$ . The experimental points are the means of duplicate estimates and the lines were plotted by computer analysis.

anatomical identity either of the labelled or the unlabelled populations of terminals. In other words, it has not hitherto proved possible to confirm that each high affinity uptake process for any particular transmitter substance is present exclusively in those nerve terminals in the brain known from independent neurophysiological studies<sup>4</sup> to release that substance.

Fortunately, the newly perfected technique for isolating large pieces of the cerebellar glomeruli with well preserved ultrastructure (glomerulus particles)5-7, now offers a preparation suitable for testing the two fundamental propositions of this hypothesis (at least for the putative transmitter GABA) namely that the high affinity uptake system is exclusively present in recognisable inhibitory endings which are known to utilise GABA as their transmitter substance and that the uptake is completely absent from other categories of nerve terminals. The inhibitory nerve terminals of the cerebellar glomeruli arise from Golgi cell axons8, and form one of the two inputs on to the granule cell dendrites. These inhibitory terminals are adjacent to the excitatory endings of the mossy fibres, which can easily be distinguished from the Golgi cell axon terminals by their large size and other ultrastructural features8.10 (Fig. 2).

The presence of a high affinity uptake process for  ${}^{3}\text{H-GABA}$  in the glomerulus particles was demonstrated in three separate experiments in which glomeruli were incubated in the presence of a wide range of GABA concentrations (1–5,000  $\mu$ M) (see Fig. 1). The  $K_{m}$  values obtained (between 7 and 12  $\mu$ M) were almost identical to those reported in slices of cerebral cortex. In addition,  ${}^{3}\text{H-GABA}$  was also taken up by a second low affinity uptake process which was characterised by a  $K_{m}$  of 780  $\mu$ M. The tissue components responsible for the high affinity uptake process were identified by electron microscopic autoradiography carried out on glomerulus particles incubated in the presence of a low concentration of  ${}^{3}\text{H-GABA}$  (2.5  $\mu$ M), thus avoiding any appreciable uptake by the low affinity process (Fig. 2). In spite of incubation in media containing

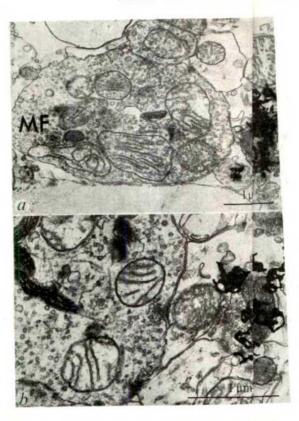

Fig. 2 a, Electron microscopic autoradiograph a lomgerulus particle showing the marked contrast lween the mossy fibre terminal (MF) which is completely ded of silver grains and the small Golgi axon on the right one picture which is overlaid by an intense cluster of silver grainb, A small portion of another glomerulus particle in which thunlabelled mossy fibre terminal and granule cell dendrite is shon to be in close morphological proximity to the intensely lalled Golgi axon terminal. The glomerulus particles (about 1-ng protein derived from six rat cerebella) were incubated in thoresence of 2.5 µM <sup>3</sup>H-GABA (specific activity 10 Ci mmol at 37 C for 6 min in 1 ml of buffered saline. After inevation, the glomeruli were centrifuged, washed, fixed in 5% glaraldehyde and processed for autoradiography<sup>3</sup>.

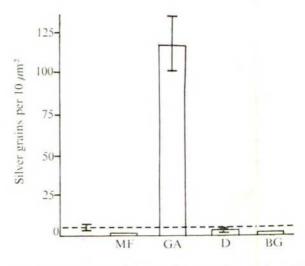

Fig. 3 Distribution of silver grains over electronmicroscopic autoradiographs of isolated cerebellar glomeruli abelled with  $^3\text{H-GABA}$ . The histogram (mean  $\pm$  s.e.) from a analysis of 15 different electron micrographs, each containing one complete glomerulus particle, to show the silver grain densityas a function of area for the various identifiable components, the mossy fibre terminals (MF), the Golgi axons (GA), the granulecell dendrites (D) and the background (BG). The dotted line shovs the average density of silver grains per micrograph, each d which was  $8\times10$  inches and represented an area of 60 q  $\mu m$ .

saline, the structure of the glomerulus particles was well

Intense cirs of silver grains resulting from the accumulation of 3H BA were found almost exclusively over small nerve termi which closely resemble the Golgi axon terminals charrised by Palay and Chan-Palay<sup>10</sup> in sections from in sitted adult rat cerebellum. Such grain clusters were never a over the adjacent mossy fibre terminals. To emphasise (selectivity of the uptake into inhibitory, as opposed to itatory terminals, a statistical analysis of the silver grain ribution was carried out on 15 electron micrographs, eacof which contained a complete glomerulus particle (Fig. The silver grain density over the Golgi axons was more tl 20 times higher than the average density per micrograph more than 100 times greater than the grain density ovehe mossy fibre terminals. The postsynaptic granule cellendrites, like the excitatory terminals, were virtually dev of silver grains.

As well aonfirming the hypothesis set out in the introduction these sults taken in conjunction with the previously reported contration of glutamic acid decarboxylase in the glomerulus picles<sup>6,7</sup> and its presence in Golgi axon terminals in situ11 suge that these inhibitory terminals retained their in vivo propes. This view is strongly supported by a parallel study12 in vch a microinjection of the GABA analogue <sup>3</sup>H-2, 4-diambutyric acid was shown to cause an identical

distribution silver grains to occur in vivo.

### Glutamatereceptors in the rat central nervous system

ALTHOUGH it is widely accepted that glutamate may be a significant central transmitter (for reviews, see refs 1 and 2), definitive neuropharmacological evidence at the synaptic level has not been forthcoming, and studies with proposed glutamate antagonists3-6 lave yielded anomalous results. On the basis of biochemical evidence, however, glutamate fulfils many of the criteria expected of a neurotransmitter; in particular, nerve endings8 and glia9,10 possess high-affinity transport systems for glutamate, which it is thought, in common with other amino acid neurotransmitters, are responsible for terminating its synaptic actions. For these high-affinity systems to function, there is a stringent requirement for sodium<sup>11</sup>, which may be involved in the initial binding phase at the reuptake site, prior to transport12-14. Until recently, very little attention has been paid to the possibility of investigating directly the biochemical properties of postsynaptic amino acid receptors. Young and

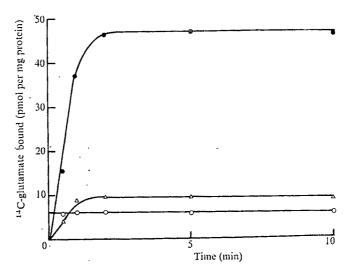

Fig. 1 Time course of binding of 14C-glutamate to synaptic membranes. Male Sprague-Dawley rats were decapitated and cerebral cortices homogenised in 20 vols ice-cold 0.32 M sucrose (Teflon homogeniser, 0.25 mm clearance, 800 r.p.m.) and centrifuged at 1,000g for 10 min. The supernatant was then and centrifuged at 1,000g for 10 min. The supernature was their centrifuged for 20 min at 17,000g to give a crude mitochondrial pellet (containing mainly myelinated axons, mitochondria and synaptosomes). The pellet (P<sub>2</sub>) was resuspended in 1.2 ml 0.32 M sucrose, which was layered on to a discontinuous gradient consisting of: 4 ml 0.8 M sucrose, 4 ml 1.2 M sucrose and 2 ml 1.5 M sucrose. Gradients were centrifuged in 6×15 ml consisting 01: 4 mi 0.8 M sucrose, 4 mi 1.2 M sucrose and 2 mi 1.5 M sucrose. Gradients were centrifuged in  $6 \times 15$  ml swing-out heads for 60 min at 112,000g. The synaptosomes were collected at the 0.8-1.2 M sucrose interface, lysed with 20 vols ice-cold distilled water in a glass homogeniser and the homogenate centrifuged for 20 min at 9,000g. The supernatant and the soft pellet were removed and recentrifuged at 50,000g. for 60 min the resulting pellet resupposed in 50,000g for 60 min, the resulting pellet resuspended in Tris-Krebs buffer, pH 7.4 (containing 50 mM Tris substituted for bicarbonate, and either 115 mM sodium chloride or 230 mM sucrose) and aliquots taken for protein estimations<sup>17</sup>. Membrane suspensions  $(6.0-6.5 \text{ mg protein ml}^{-1})$  were stored at  $-30^{\circ}$  C, no significant loss of binding activity was detected after 2 months.

Synaptic membranes (0.31-0.35 mg protein ml-1) were incubated in 0.5 ml Tris-Krebs medium (with or without sodium<sup>+</sup>) at 25°C and containing 1.75×10<sup>-6</sup> M L-U
<sup>14</sup>C-glutamate (Amersham) for periods of time from 30 s to <sup>14</sup>C-glutamate (Amersham) for periods of time from 30 s to 10 min. Membranes were recovered by rapid (approx 5 s) vacuum filtration through Whatman GF-C glass fibre filters followed by rinsing with 5 ml Tris-Krebs. Filters were transferred to vials and the tissues digested with 0.4 ml Soluene-100 (Packard) prior to addition of fluor for liquid scintillation counting. To correct for binding of <sup>14</sup>C-glutamate at sites other than for uptake and the postsynaptic receptors (that is, nonspecific binding), the binding of <sup>14</sup>C-glutamate was studied in the presence of a large molar excess of unlabelled L-glutamate. This nonspecific binding was not saturable and increased proportionately with increasing <sup>14</sup>C-glutamate increased proportionately with increasing <sup>14</sup>C-glutamate concentration. In all experiments to determine specific glutamate binding, this nonspecific component was subtracted. The effect of synaptic membrane protein concentration on specific 14C-glutamate binding was also investigated and was found to be linear over the range studied (0.2-0.5 mg protein ml<sup>-1</sup>).

•, Specific <sup>14</sup>C-glutamate binding in the presence of sodium;

△, specific <sup>14</sup>C-glutamate binding in sodium-free medium;
⊙, nonspecific <sup>14</sup>C-glutamate binding (blank values, <sup>14</sup>C-glutamate bound to filters in absence of tissue subtracted from each value) determined in the presence of unlabelled glutamate  $(5 \times 10^{-3} \text{ M})$ . Results are means of quadruplicate determinations; s.e.m. all <10%.

Snyder<sup>15</sup> have demonstrated that strychnine, a potent and selective antagonist of glycine-induced hyperpolarisations of spinal neurones, binds specifically to a component of synaptic membranes; this is probably the physiological glycine receptor since strychnine has negligible affinity for the glycine highaffinity uptake system. The specific γ-aminobutyric acid (GABA) antagonist, bicuculline, has also been found to competitively inhibit GABA binding to synaptosomes, in which the uptake site had been inactivated by chlorpromazine 16. In both these cases, binding to the postsynaptic receptor was not affected by the absence of sodium.

I have therefore examined the possibility that in the absence of sodium, the characteristics of the still hypothetical, specific glutamate receptor on synaptic membranes might be investigated.

Figure 1 shows the time course of specific 14C-glutamate binding at 25° C and, in common with the binding of strychnine to glycine receptors, nonspecific binding was not time dependent (essentially instantaneous), whilst the specific binding was rapid, with a plateau after 2 min. Half maximal binding occurred within 30 s, both in the presence and absence of sodium. When binding was studied at 0° C, maximal binding was not apparent for 8 min. All further binding studies were carried out with a 5 min incubation period.

Kinetic characteristics of specific glutamate binding were then examined under two experimental conditions: (1) in normal Tris-Krebs medium containing N-methyl-pL-aspartate (10<sup>-3</sup> M), a highly potent glutamate agonist<sup>18</sup> with no affinity for the glutamate uptake system<sup>19-21</sup>; and (2) in sodium-free Tris-Krebs medium. Such a scheme should theoretically permit assessment of binding to the uptake and receptor sites individually. Binding was measured over a restricted range of  $^{14}$ C-glutamate concentrations  $(4 \times 10^{-7} - 8.7 \times 10^{-6} \text{ M})$  and

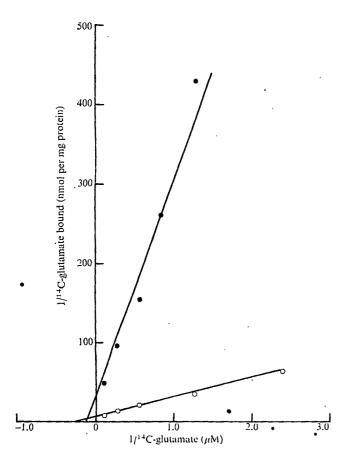

Fig. 2 Lineweaver-Burk plots of 14C-glutamate binding to cortical synaptic membranes in Tris-Krebs medium containing N-methyl-DI-aspartate (10<sup>-3</sup> M) (O) and in sodium-free medium ( ). Lines of best fit by regression analysis. Each point is the mean of quadruplicate determinations; s.e.m. all  $\leq 10\%$ .

the double reciprocal plots (Fig. 2) reveal apparerissociation constants (pKs) of  $4.0 \times 10^{-6}$  M and  $8.3 \times 10$ M for the uptake and receptor sites respectively.

If there are subtle configurational differences netween the postsynaptic glutamate receptor and the presiptic highaffinity uptake site, an investigation of specific -glutamate binding to synaptic membranes in the presendbinding to both sites) and absence (binding to receptors ly) of Na+ should readily provide the means of distinguing between glutamate agonists and the highly elusive glutamaintagonists. Acidic amino acids such as N-methyl-DL-artate and D-homocysteate, with strong excitant action on central neurones, are not substrates for the high-anity uptake system19-21-a property shared only with the five corounds which have been suggested as effective antagonists | glutamateinduced and some synaptic excitations in the NS, that is, glutamic acid diethylester<sup>4,5</sup>, α-methyl-DL-glumic acid<sup>3</sup>, 1-hydroxy-3-aminopyrrolid-2-one (HA-966)6, 2-methoxyaporphine and L-methionine-DL-sulphoximine in contrast, medium excitants, such as L-glutamate, L-asparte, L-cysteate and L-homocysteate, are all potent blockers chigh-affinity glutamate uptake. Table 1 shows the effects of N+ on specific L-glutamate binding and how this can be maffed by the presence of some glutamate congeners. Binding itereospecific as evidenced by the lack of competition by D-glumate, which is a weak excitant with minimal effects on uptal, L-aspartate produced a marked inhibition of binding at bo sites, while DL-homocysteic acid (DLH) showed a greateieffect at the glutamate receptor than at the reuptake site. DLH i considerably more potent as a neuronal excitant than is eithe L-glutamate or L-aspartate18, and my results suggest that his may be attributable to the lesser ability of DLH to bindo the uptake site, than either glutamate or aspartate, since s affinity for the glutamate receptor appeared to be equivalnt to that of L-aspartate. Glutamic acid diethylester, one of the more effective glutamate antagonists, had no effect a the specific binding of 14C-glutamate at the uptake site, bt produced a highly significant inhibition of binding at thereceptor site. Finally p-chloromercuriphenylsulphonate, a sustance which at low concentrations potentiates the synaptic ations of both excitant and inhibitory amino acids, possibly by inhibiting their reuptake<sup>22</sup>, produced some reduction of speific glutamate binding at both sites. These effects were probally nonspecific, since mercurials combine extensively with the subhydryl groups of membrane components23,24.

These results support the idea that specific gluamate binding to its postsynaptic receptor may be distinguished from binding

to its uptaite by its independence of sodium. I am now investigatine effects of a wide range of potential glutamate antagonists the specific binding of glutamate, and attempts will be n to isolate and characterise these binding components has been done for the insect glutamate receptor25.

I thankt J. C. Watkins (Bristol) for his gift of N-methyl-partate.

#### Human x mouse hybrid cells segregating mouse chromosomes and isozymes

THE usual patern of chromosome segregation in interspecific human x moue somatic cell hybrids is retention of mouse and loss of human chromosomes1. In attempts to generate hybrid strains expressing differentiated functions, we have fused an actively dividing human cell line with freshly dissociated, highly differentiated cells from the mouse embryonic nervous system. The majority of the resulting hybrid strains retain human while losing mouse chromosomes and isozymes and thus provide a new class of hybrid cell for analysis of gene linkage and regulation.

The human fibroblast parent used was WI-18-VA2 (VA2)<sup>2</sup>, a SV40-transformed clonal derivative of WI-18, deficient in

Cells were grown in modified F125 medium (F) or Dulbecco's modified Eagle's medium (D), supplemented with 5% foetal calf serum and, as indicated, HAT (FHAT, DHAT), in an atmosphere of 5-10% CO<sub>2</sub>, 90-95% air with 95% relative humidity, at 37 C in Falcon plastic ware. Parental VA2 cells after growth in 100 µM 6-thioguanine-supplemented medium formed < 1 × 10<sup>-7</sup> colonics per inoculated cell in FHAT, while parental mouse pervious system. o-thioguanine-supplemented medium formed  $< 1 \times 10^{-7}$  colonics per inoculated cell in FHAT, while normal mouse nervous system cells formed  $1-5 \times 10^{-7}$  colonies per inoculated cell in FHAT. Trypsinised, washed, VA2 cells  $(3 \times 10^{9})$  were mixed with normal mouse cells  $(10^{4}-5 \times 10^{9})$  in serum-free medium (1 ml) and fused with 200–500 haemagglutinating units (0.03% chick red blood cells of  $\beta$ -propiolactone-inactivated Sendai virus, 10 µg DNase I, as before Washed, fused cells were either diluted immediately in medium into many 100 mm dishes or seeded into one dish and then trypsinised and many 100 mm dishes or seeded into one dish and then trypsinised and distributed 24 h later. All cells were transferred to FHAT medium 24 h after fusion, fed every 4 d with FHAT, and hybrid colonies were isolated 18-24 d later as independent mating events by trypsinisation in penicylinders (Fischer Scientific Co.). Many lines were recloned before testing (indicated by letter suffixes of clone name). Cells were about trypsinisation expensionally case a week and interpretable to the control of the control o subcultured by trypsinisation approximately once a week and intermittently stored in the vapour phase of a N<sub>2</sub> freezer with 7.5% dimethylsulphoxide (DMSO) or 5% DMSO and 5% glyccrolsupplemented medium Chromosomo provides and the control of the contro supplemented medium. Chromosome preparations were prepared by arresting logarithmic phase cells (50-100 doublings after fusion) in 0.02 µg ml<sup>-1</sup> colcemid for 4 h, swelling in 75 mM KCl, air drying and then scoring 20-40 metaphases per cell line using a camera lucida attachment on a Wild microscope. Embryonic mouse brain (18 d in utero) was dissociated, cultured in DHAT for 2 weeks, and then scored. Eighty-six per cent of the cells had 40 chromosomes, 2% had 37, 6% had 50, and 6% had 80 chromosomes.

hypoxanthine phosphoribosyltransferase (HPRT) and thus unable to grow in HAT-supplemented medium3. A suspension of parental mouse cells was obtained by dissecting specific anatomical regions of C57BL/6 or NIH/Swiss-GP 15-18 d in utero embryonic mouse nervous systems, pooling the same regions from one litter, and then dissociating cells in trypsin, collagenase and DNase4. Cells were used for fusion directly (VM series) or incubated overnight in complete medium and the non-attached cells collected (VMP series).

Using Sendai virus (legend of Table 1) hybrid cell lines were generated repeatedly in fusions between human VA2 cells and cells freshly derived from the embryonic mouse, rat or Chinese hamster nervous system resulting in the same pattern of reverse chromosome segregation; however, only data on human-mouse hybrids are presented here. Approximate yields were  $3 \times 10^{-5}$  hybrid colonies per VA2 parent and  $2 > 10^{-5}$  per normal rodent nervous system cell put into the fusion. The cells appeared fibroblastic, not similar in morphology to mouse neuroblastoma cells6, and all were negative when stained acetylcholinesterase<sup>6</sup> (1,850 colonies scored). The population doubling times (and plating efficiency) of hybrid cell lines varied widely and representative samples were studied.

In the VA2 × mouse nervous system cell lines the number of biarmed and presumably human chromosomes was greater than the human diploid value (2n = 46) and similar to that of VA2 (Table 1). In contrast, the number of telocentric (mouse)

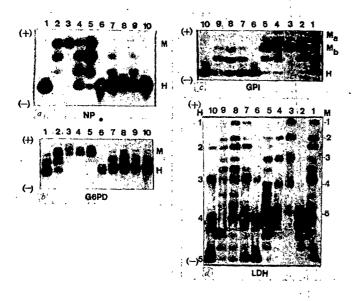

Fig. 1 Zymograms for: (a) nucleoside phosphorylase; (b) glucose 6-phosphate dehydrogenase; (c) glucose phosphate isomerase; (d) lactic acid dehydrogenase. M, mouse; H, human pattern. In (c), Ma and Mh indicate migration of mouse GPI-1A, and GPI-1B isozymes and the hybrid cell in slot 4 was derived from fusion of a VA2 cell to a mouse cell (NIH/Swiss GP) heterozygous (GPI-1AB) at this locus. In (d), 1, 2, 3, 4, 5 indicate mobility of human or mouse LDH isozyme bands alone. Cell lines were: 1, VMPTH12H; 2, VB3A; 3, C57BL/6 mouse embryo brain; 4, VMSG11; 5, VMSC24, 6, VA2; 7, VMPTH14D; 8, VMPTH12; 9, VMPOC15M; 10, VMPTH28G. Note that hybrid lines in slots 4 and 5 were preselected for retention of telocentric and loss of biarmed chromosomes, and thus represent an uncommon class while slot 2 is a VA2 × L-cell hybrid.

chromosomes was less than the mouse diploid value = 40). Because some human D and G group chromosomes in VA2 may be confused with mouse telecentric chromes, the mouse chromosomes in these hybrid cells make been overestimated. Karyological analysis by quinar mustard chromosome banding shows that translocation mouse chromosomes does not occur frequently enough interfere with these estimates (our work in preparation).

Sixty to one-hundred population doublings aftision, the hybrid strain phenotypes for 16 isozymes wertermined (Table 2, Fig. 1). The genes for the human isozs studied have been assigned to specific human chromosonncluding: 1, 2, 6, 7, 11, 12, 14, 18, 19, 20, 21 and X13. Mosthe hybrid lines continued to express all the human isozynbut failed to express certain of the mouse isozymes. A fremained balanced, expressing all the human and molisozymes tested. These balanced hybrid lines had fer than 40 telocentric chromosomes. In hybrid cell lines a reduced numbers of telocentric chromosomes, the hur isozymes exhibited equal or greater staining activity than thomologous mouse enzymes which contrasts with previousork with human x mouse hybrids (slot 9, Fig. 1). Hepolymeric isozyme bands of intermediate mobility were notor PEP A (DIP-2), cytoplasmic GOT, LDH A, MDH BPI, IPOdimeric, NP, IDH1, and G6PD in these hybrics reported for other human x mouse hybrids 13-15, which pports the homology of the markers for scoring purposes. few hybrid strains retained telocentric and lost biarmed comosomes (less than 5% of the total lines tested) and the segregated human isozymes (Table 3). In contrast, m than 50 VA2×mouse L-cell hybrids made by us ha segregated human while retaining mouse markers, suggest that the SV40 genome in VA2 is not the main determininactor in loss of mouse chromosomes.

Cells were shifted from F to D medium with or without HAT supplementation depending on their ability to grow in HAT. For unexplained reasons, not all hybrid cell lines were capable of growth in DHAT after growth in FHAT (plating efficiency < 10<sup>-5</sup>) in spite of the ability of VA2 to grow well in either F or D medium. The cell lines were free of mycoplasma contamination by bacteriological analysis (dicrobiological Associates). Cells at confluence were washed three times with saline D<sub>1</sub> supplemented with 5.6 mM glucose, and 59 mM sucress sonicated at 4° C in 50 mM KPO<sub>4</sub>, pH 6.8 (total homogenate protein concentrations?, 10-20 mg ml<sup>-1</sup>) frozen on dry ice, stored under the vapour phase of a N<sub>2</sub> freezer. Brains from C57BL/6 6-week-old makes, or 16-18-d in utero embryos were processed similarly. Thawed homogenates were centrifuged (30,000g, 30 min, 4° C) and 250-500 µg of supernatant fluid protein was used per slot in a Buchler vertical starch ge electrophoresis using Electrostarch (Otto Hiller) and isozymes were scored by standard procedures 8-12: lactic dehydrogenase A and B (LIH A, LDH B); peptidase B (PEP B, mouse TRIP-1); peptidase C (PEP C, mouse DIP-1); peptidase A (PEP A, mouse DIP-2); glucose 6 phosphate dehydrogenase (GPD); indophenol oxidase dimeric (IPO-A); mannose phosphate isomerase (MPI, mouse MPI1); nucleoside phoshorylase (NP); hexokinase (HK); adenosine dearminase (ADA); cytoplasmic glutamate-oxaloacetate transaminase (GOT1, mouse GOT1; glucose phosphate isomerase (GPI); isocitrate dehydrogenase (IDH1, mouse ID-1); cytoplasmic NAD dependent malate dehydrogenase (MDH1; phosphoglucomutase 1 (PGM<sub>1</sub>, mouse PGM<sub>2</sub>). LDH B is activity of band 1 (see Fig. 1d) relative to VA2. HAT column in the tables incicates the ability of cell line to grow in HAT medium. Mouse isozyme nomenclature, when available, is used in this table. N = No activity; cash = uncertain.

These hydrines were preselected from over 100 VA2 × mouse nervous system hybrids for retention of telecentric and loss of biarmed chromosoma these few lines, the mouse isozymes were always expressed and the (+) and (-) symbols refer to the expression of human isozymes. V = VA2 × B82 (mouse L cell) hybrid line is presented for comparison as an example of a VA2 × mouse tissue culture line. Human isozyme nomenclature is used in this table.

Hybrid cretaining human and losing mouse chromosomes provide inflation for mouse linkage studies. Our data from VA2×mouhervous system hybrids suggested associations of mouse ismes (Tables 2 and 4). Mouse GPI, associated with mouspkage group (LG) I11, exhibited an apparent synteny wiLDH A and TRIP-1 (human nomenclature, PEP B). Inher experiments, Chinese hamster fibroblast × normal motspleen hybrids segregating mouse chromosomes and isozymhave yielded a few examples of asynteny of expression couse GPI, TRIP-1, and LDH A (in preparation). Pitfalls exi in somatic cell linkage analysis including non-randomgregation of chromosomes<sup>16</sup>. In fact, since some isozymes weexpressed more frequently than others, our data suggest nonndom segregation of mouse markers in this system. Syny data should be considered tentative and the presence or sence of specific mouse chromosomes must be demonstrateo be correlated with specific mouse isozymes.

Eight hylls between VA2 (HPRT-) and mouse nerve tissue (HPR+) that had lost telecentric chromosomes were removed fro HAT medium about 40 doublings after fusion,

1

grown in medium F for forty doublings, and then found to be unable to grow in HAT medium. When tested for G6PD, apparent synteny was noted between the ability to grow in HAT and expression of mouse G6PD. It will be interesting to determine if mouse HPRT and G6PD are correlated with the presence of the mouse X chromosome as they are with the human X chromosome<sup>13,17</sup>.

Several examples of asynteny of mouse isozyme expression, generated from the data in Table 2, are summarised in Table 4. With the exceptions of GPI, LDH A and TRIP-1, the other mouse isozymes appeared to be asyntenic with each other. Thus, these isozymes probably mark 12 of 19 mouse autosomes. One case is perplexing and emphasises the need for caution in interpreting the results. DIP-1 and IDH-1 have both been assigned to LG XIII in the mouse<sup>11</sup>. Yet, three instances of asynteny were detected in hybrid clones (Table 4). In all cases, DIP-1 was expressed while IDH-1 was not, possibly due to weak staining of mouse IDH-1.

The data in Table 2 were collated for 22 hybrid clones segregating mouse chromosomes that arose as independent mating events or exhibited differences in their isozyme patterns. The number of cases of lack of correlation (asynteny = +, -, or -, +) between two different isozymes was tabulated. In the case of LDHB (LDH1) where mouse and human phenotypes cannot be distinguished but VA2 has low LDH1 levels only +++ or ++ activity was used as positive, and (-) used as negative. Mouse isozyme nomenclature is used in this table.

chromosome 2, and LDH B and PEP B with chromosome 12 have been reported<sup>13</sup>. VA2-mouse nervous system hybrids have yielded examples of asynteny of expression in the mouse for each of these isozyme pairs. Thus our studies suggest interspecies differences in these linkage relationships. We anticipate, however, that interspecies homology may be detected when markers short map distances apart or on the X chromosome are considered.

Jami et al.18 presented preliminary evidence of a case of retention of human and loss of mouse chromosomes in one and possibly two rare hybrids formed by fusing VA2 to mouse tissue culture L cells. In their report, however, no data were presented (such as absence of a mouse isozyme) which would imply loss of both homologues of any of the mouse chromosomes. Most of their VA2×L-cell hybrids, as well as similar hybrids produced by Weiss et al.2 retained mouse and lost human chromosomes. Our results describe a general method (fusion of freshly liberated mouse cells with an established line of human cells) for producing reverse segregant hybrids as well as evidence that such strains do lose mouse chromosomes and isozymes.

The isozymes we studied were codominantly expressed in at least some hybrids from these matings and in hybrids of the type that retain mouse and lose human chromosomes<sup>13</sup>. It is likely for most isozymes studied that chromosome segregation, and not gene regulation, is responsible for the lack of expression. In addition, molecular hybridisation studies have demonstrated that mouse nuclear DNA can be lost altogether from such hybrids4. When mouse isozymes capable of codominant expression are not detected in hybrid cells, presumably both chromosome homologues have been lost from the cell line. Miller19 has shown in man-mouse hybrids segregating human chromosomes, however, that considerable heterogeneity of human chromosome complements can exist within a hybrid line in spite of a constant mean number of human chromosomes per cell. Thus, the total number of different chromosomes represented within a line may be quite large. Similar analysis will be needed of hybrids segregating mouse chromosomes.

The basis for the novel pattern of chromosome and isozyme segregation in these hybrids is undetermined. It does not appear to be a unique property of VA2 since similar results were obtained with human cell D98AH-2 (American Type Culture Collection CCL18.3). Nor are embryonic cells unique; adult mouse bone marrow and spleen cells also give reverse segregating hybrids with VA2. The nervous system cell fused (for example neurone or glia) is not known; however, further study of differentiated functions in the hybrids may establish their parentage. Since these hybrid strains retain complete human chromosome complements, they represent new combinations of human and mouse genetic information for work such as analysis of mitochondrial DNA composition<sup>4</sup> or study of viral gene regulation 20.

We thank A. Rahe, S. Stephenson, J. Silidker and D. Berkely and Drs G. D. Trisler and H. C. Coon for assistance. We thank Dr T. Shows for discussing isozyme methodology with us.

#### Activation of low molecular weight fragment of antihaemophilic factor (factor VIII) by thrombin

THE precise molecular function of plasma alaemophilic factor (AHF, factor VIII), a glycoprotein with apparent molecular weight of 2 × 105, is unknown. Recessperiments suggest that this function may be carried out by av molecular weight (LMW) fragment which can be dissociaterom plasma AHF by increased salt concentration1-3. The LW fragment retains procoagulant activity, but is not reactivn immunoprecipitation assays for AHF-related antigen4. A ih molecular weight (HMW) fragment, also identified using h salt conditions, has no procoagulant activity but retainAHF-related antigen in immunoprecipitation assays and vi Willibrand factor activity in washed platelet assays4,5. We he now found that the LMW fragment, as well as AHF8-9, isisceptible to activation by thrombin. This observation sugsts that the LMW fragment is not a product of thrombin actition of AHF and verifies the proposed role of the LMW fragent in AHF procoagulant activity.

Partially purified AHF was obtained by agaroigel filtration of an AHF concentrate (Abbott Laboratories, Sth Pasadena) using the method of van Mourik and Mochtar! AHF in the void volume fractions was concentrated by adng an equal volume of 30% polyethylene glycol (PEG); the ecipitate was separated by centrifugation at 39,000g at 20° C r 30 min and was redissolved in one-tenth the original volumin imidazole

Table 1 Thrombin activation of AHF and LM\fragments

Incubation time	AHF activity (U 1-1)						
(min)	Purified AHF*	LM\ fragments*					
0	1.0	1.0

70	0.3	1.0					

<sup>\*</sup> Material was diluted in barbital-buffered salir4 so that each contained 1 U ml<sup>-1</sup> AHF activity. To each was aded 1/20 volume phospholipid (final concentration 0.05 mg ml<sup>-1</sup>) ad 1/20 volume purified thrombin (final concentration 0.035 U ml<sup>-1</sup>). The mixture was incubated for 3 min at 37° C and then placed in at ice water bath. Samples were removed for AHF assays<sup>12</sup> at the specified times. AHF activity before addition of thrombin is identified a 0 min. Control activity before addition of thrombin is identified a 0 min. Control assays were carried out in which thrombin and piospholipid were added to buffered saline. This mixture had an appaent AHF activity less than 0,001 U ml-1 and was not different from the blank time.

\* Materia ted in barbital-buffered saline so that each contained 1 U of AHF-related antigen by radioimmunoassay 13. Assay edure was otherwise as described for Table 1.

(0.05 M)-bled saline (0.14 M) pH 6.8. This sample was dissociated tel filtration in 0.24 M CaCl, and 0.05 M imidazole, pH 6 sing a Bio-Gel A-15m (BioRad) column of  $1.6 \times 30$  cnth a flow rate of 20 ml h<sup>-1</sup> at room temperature<sup>4</sup>. HMW and W fractions were pooled separately and concentrated with equal volume of 30% PEG as indicated above; the precipit were each dissolved in one-tenth the original pool volumin imidazole-buffered saline. Bovine thrombin (Parke-Daylas purified by Lundblad's method<sup>11</sup>. The specific activity of thrombin was 1,333 U mg<sup>-1</sup> as determined by a reference cu prepared with standard thrombin supplied by Dr David Ason (Bureau of Biologics Standards, Bethesda).

Thrombirtivation of AHF and the LMW and HMW fragments was amplished as described in Table 1. Activation of AHF and IW fragment was maximal after 3 min, the procoagularactivity increasing tenfold over the starting activity (Tal 1). Subsequent inactivation of procoagulant activity was's marked for the LMW fragment than for purified AHF. Rults were similar in three experiments.

Low levels AHF procoagulant activity were also detected 3 min after tombin activation of the HMW fragment. Table 2 presents rest from a typical experiment; shortening of the clotting timevas observed in five instances. Thrombin activation of the MW fragment may indicate incomplete dissociation of the MW from the HMW fragment. Alternatively, masked pot(ial procoagulant activity may be exposed by alteration of inactive HMW fragment by thrombin.

Thus AH ragments produced by dissociation in high ionic strength buffs retain the capacity for thrombin activation and inactivation. The demonstration that thrombin activates the LMW fragmit provides additional evidence that this part of the AHF coolex is important for AHF procoagulant activity as measured vitro. A corresponding physiological role for LMW AHFragments is suggested by the detection of low molecular wight procoagulant activity after transfusion in patients withon Willebrand's disease14.

The molellar basis for thrombin activation of AHF and the LM7 fragment derived from AHF—is unknown. As the LMW frement retains a capacity for thrombin activation, it is unlikely be a product of thrombin action on intact AHF. The absenceof detectable proteolytic products when highly purified AHFis activated by thrombin<sup>15,16</sup> supports this conclusion. Thromin activation of AHF is an important but poorly understood penomenon; studies with LMW fragments will permit more robing analysis of this interaction.

We thank Carol Church for technical assistance. These studies were supported in part by grants from the National Heart and Luig Institute and the Connecticut Chapter, National Hemophilia foundation of which M.E.R. is a postgraduate research fellov.

#### Myosin linked calcium regulation in vertebrate smooth muscle

CONTRACTILITY resulting from the interaction of actin and myosin filaments is in general controlled by the concentration of calcium ions. The regulation of this interaction by Ca ions can, in principle, be exercised at the level either of the actin or of the myosin filaments and both these types of regulatory system are found in nature. In vertebrate skeletal muscle troponin is the Ca receptor and is attached to the actin filament. The action of troponin is inhibitory: when no Ca ions are bound to it the interaction between actin and myosin is prevented1-4. This inhibition is relieved and interaction occurs at calcium concentrations sufficient for the Ca binding sites on the molecule to be occupied. The second type of regulatory system was discovered in molluscan muscles and is present in other invertebrate systems which lack troponin5,8. In some cases both types of regulation seem to be present in the same muscle<sup>9.7</sup>. Here I present evidence which shows that such a myosin-linked regulatory system is not confined to invertebrates but is also present in smooth muscles of higher vertebrates. A more detailed description of the regulatory system in this muscle type is presented elsewhere8,8.

Rabbit actin filaments without regulatory proteins attached have been used in a diagnostic test for the presence of myosinlinked Ca regulatory systems6. The principle underlying this competitive actin-binding assay is that if an actomyosin contains Ca-regulated myosin filaments, the ATPase activity of the preparation will not be stimulated when unregulated actin filaments are added; Ca ions will still be required for activation. This is the case when purified rabbit actin filaments<sup>10</sup> are added to smooth muscle (chicken gizzard) actomyosin (Table 1). The ATPase activity shows the identical sensitivity to Ca both in the presence and absence of a molar excess of actin molecules. Other experiments have established that actin and myosin of smooth muscle actomyosin dissociate under the conditions used in this experiment and thus the myosin molecules were free to complex with the added skeletal muscle actin. The turbid smooth muscle actomyosin undergoes a dramatic clearing reaction when ATP is added, coincident with the dissociation of actin and myosin. Observation of a reaction mixture indicated that no incipient precipitation occurred when the actin filaments were added and therefore that the actomyosin remained dissociated. Since Ca is required for stimulation of the ATPase activity in the presence of unregulated skeletal actin, the absence of Ca must have a direct effect on the myosin which prevents its interaction with actin. Precisely how Ca determines whether or not the myosin will combine

Weiss, H. J., and Kochwa, S., Br. J. Haematol., 18, 89-100 (1970).

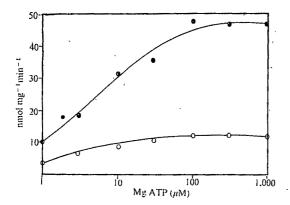

Fig. 1 The rate of ATPase activity was determined using a creatine kinase ATP regenerating system<sup>3</sup>. The reaction medium contained 60 mM KCl, 20 mM imidazole (pH 7.0), 5 mM creatine phosphate, 0.5 mg ml<sup>-1</sup> creatine kinase and 5.3 mg ml<sup>-1</sup> GAM, 1 mM MgCl<sub>2</sub>, 0.5 mM cysteine, and either 2mM EGTA or 100 µm CaCl<sub>2</sub>. The MgATP concentration indicated is the added concentration, the myosin concentration is about 7.3 µM. ATP was added as the Mg chelate, and therefore the Mg<sup>2+</sup> concentration, was 1 mM throughout the experiment. The reaction time varied between 3 and 30 min at 25° C. ●, +Ca; ○, -Ca.

with actin is not understood; it could be through an electrostatic effect or through a conformational change in the molecule.

In vertebrate smooth muscle preparations, no troponin-like components can be identified by SDS gel electrophoresis8,9, But to demonstrate the absence of troponin by another, independent method, a functional test, which is essentially the converse of the experiment above, was carried out. For this experiment rabbit heavy meromyosin (HMM) which itself is not calcium responsive was mixed with the smooth muscle actomyosin (Table 1). If no Ca regulatory system is present on the actin filaments the HMM ATPase activity would be expected to be unrestrained at low Ca concentrations; otherwise it would be inhibited. As expected of an actomyosin without Ca-regulated actin filaments, the ATPase activity after HMM addition is less sensitive to Ca than the control.

Subtracting the contribution of the smooth muscle actomyosin from the total activity shows that the actin stimulation of the HMM ATPase activity is actually depressed in 100  $\mu M$  Ca. Since the smooth muscle actomyosin superprecipitates in the presence of 100 µM Ca, this depression can be accounted for by the complexing of the smooth muscle

Table 1 Locus of the calcium regulatory system in smooth muscle actomyosin

Components	nmol m		Ca sensitivity (Activity 10 <sup>-4</sup> M Ca)
	10 <sup>-9</sup> M Ca <sup>2+</sup>	10-4M Ca <sup>2+</sup>	(Activity 10 <sup>-9</sup> M Ca)
(a) Gizzard actomyosin (GAM) (1.3 mg ml <sup>-1</sup> )	4.1	21.7	5.3
(b) GAM (1.3 mg ml <sup>-1</sup> )+ rabbit actin (1 mg ml <sup>-1</sup> )	4.4	23.2	5.3
(c) GAM (1.3 mg ml <sup>-1</sup> )+ rabbit actin (1 mg ml <sup>-1</sup> ) +chicken breast	4.4	23.1	5.3
tropomyosin (0.2 mg m)			
(d) GAM (1 mg ml <sup>-1</sup> )+ Rabbit HMM (0.5 mg m	29.1	39.7	1.4
(e)(d)-(a)	25.0	18.0	; <b>0.7</b>

The weight ratio of tropomyosin:actin: myosin in the smooth muscle actomyosin is approximately 0.3:1.0:2.4 (ref. 8). The ATPase activity was determined by phosphate liberation after mixing gently for 10 min at 25° C in a medium containing 1 mM MgATP, 40 mM KCl, 20 mM imidazole (pH 7.0), and either 1 mM EGTA or 100  $\mu$ M CaCl<sub>2</sub>. The rabbit actin filaments and the chicken breast tropomyosin were determined to be free of contaminating proteins by SDS gel electrophoresis analysis. In (D) the rate of HMM ATP hydrolysis in the absence of actin (3.4 nmol ml-1 min-1) has been subtracted and thus the values given are actin-stimulated activities.

myosin with a fraction of the actin molecules, thereducing the number available to stimulate the HMM AT activity.

Another distinguishing feature of actin-linked ared with myosin-linked regulatory systems is their respon changes in MgATP concentrations11. Relaxation of skl muscle systems does not occur at low MgATP concentratiwhere the myosin active sites are not saturated with sate. The raised ATPase activity3,4,12 and persistence offtraction13 which occur under these conditions is indirectlyjed by the substrate-free myosin molecules. They form rigiomplexes with actin and nullify the inhibitory influenf Ca-free troponin3.4. If myosin is subject to Ca regulation, sa biphasic response-stimulation at low and inhibition ath MgATP concentrations-is not expected and is not foun myosinlinked regulatory systems11.

Smooth muscle actomyosin responds in a manypical of a myosin-linked regulatory system; the response it biphasic. ATPase activity at the low Ca concentration incremonotonically, and is Ca sensitive (that is, relaxationurs, at all MgATP concentrations even when the numbof myosin molecules exceeds that of substrate molecules) (11). Similar results have been obtained in superprecipitation periments with actomyosin and in ATPase activity meaments and superprecipitation experiments with smooth mulmyofibrils.

My results are consonant with those of Filoal.14 where tension measurements were performed at diffit MgATP concentrations on guinea pig taenia coli. In thetudy, however, the concentration of MgATP was chan by adding various amounts of Mg to a constant amount ATP. The interpretation of the data obtained under thesonditions is not straightforward because the ATP anion has daxing effect on smooth muscle8,8,15, and also because Mg ionave specific effects on smooth muscle contractile apparatus8. he results of these workers indicate nevertheless, that myosiegulation is not restricted to chicken gizzards.

The above results indicate that the myosin ked calcium regulation found in primitive organisms has en retained during the evolution of higher vertebrates. Bothpes of regulatory system have evolved in parallel and are preit in different types of muscle in the same animal. In view ohe similarity between the myosin of smooth muscle and that fri non-muscle sources, especially with respect to their immungical characteristics16,17, and with respect to the light chaisize8,9,18-21 it is not unlikely that a similar mode of Ca regulon is present in these other systems as well. If this can be subintiated, then the study of smooth muscle, which is more reily available, will throw light on these other less well deed forms of contractility.

This work was done during the tenure of a Rearch Fellowship from the Muscular Dystrophy Association of America. I thank Dr Michael K. Reedy for comments on a manuscript, helpful discussions, and support on his Nation Institutes of Health and Muscular Dystrophy Association ants. I thank Dr W. Longley and Mr W. Garrett for readingle manuscript and Dr Apolinary Sobieszek for stimulating dijussion.

#### Calcium hophore A23187 potentiate witch and intracellular calcium release iningle muscle fibres

THE potentian by drugs of the twitch force in skeletal muscle has generallyeen related to a prolongation of the 'active state' in thexcitation-contraction coupling mechanisms1.2. This can, hower, only be partially correct since in another type of potention elicited by repetitive stimulation (staircase phenomenon the 'active state' was found to be intensified but not proliged3. This view that the 'active state' is not maximum in lingle twitch and that it can indeed be intensified in twitch poteiation was criticised but subsequently received support from everal studies 5,6. On the other hand it is well known that tivation of muscle contraction involves rapid changes of e intracellular calcium concentration which result from ceium release and uptake processes in the sarcoplasmic reticum (SR)<sup>7,8</sup>. The discovery of specific ionophores (antibiotics abwing cations to cross biological membranes by way of a frly electroneutral mechanism) which selectively increase the jembrane permeability to calcium9-11 offers a new tool following these intramuscular processes. For example, ionohore X537A was found to alter the contractile responses an resting tension of strips of rat diaphragm, an effect which as ascribed primarily to an increased calcium influx across he muscle fibre membrane<sup>12</sup>. On the other hand the ionophore X537A and A23187 tested on SR vesicles and mitochondriaisolated by ultracentrifugation were found to induce a release of stored calcium10.12.13.

The present nvestigations indicate that the calcium ionophore A23187 (Eli killy) strongly potentiates the twitch force of single muscle ibres and acts directly on the process of calcium release from the SR, even in these intact fibres. The experiments were performed on muscle fibres isolated from the depressor muscles of the barnacle, Balanus nubilus, in conjunction with two different procedures as described recently14: (a) the intracellular concentration of calcium ions at rest and during activation was studied in large fibres 1.0 to 2.0 mm diameter which had ben micro-injected with the calcium-sensitive bioluminescent protein aequorin15 and placed in a light-tight chamber in flont of an EMI 9635 photomultiplier tube; (b) the calcium putflux across the outer membrane was estimated in single barnacle fibres loaded by an intracellular injection of 0.1 to 0.2  $\mu l^{1.45}$ Ca in Tris buffer at pH 7.2 (ref. 16). The calcium ionophore A23187 was dissolved at 10<sup>-3</sup> M in ethanol

which was added to artificial seawater (ASW) to obtain a final concentration chosen from  $10^{-7}$  to  $10^{-5}$  M.

Figure 1 illustrates the resting calcium outflux from a single barnacle muscle fibre equilibrated in ASW, two hours after <sup>45</sup>Ca loading. Ethanol 1% added to the external medium was found to increase the resting outflux by 90% above baseline. At these concentrations the ethanol effect reached its maximum in about 30 min. After this control test A23187 10-5 M in ASW (thus containing also 1% ethanol) was substituted externally: the resting calcium outflux increased markedly to reach a new level, 450% above the extrapolated baseline. The maximum increase of calcium outflux induced by A23187 was usually observed after 30 to 50 min in 10<sup>-5</sup> M A23187. The increase of 45Ca outflux was recorded in all experiments but its amplitude depended upon the ionophore concentration; the recovery on return to ASW was influenced both by the duration of exposure and by the concentration used. The findings cannot be explained by an increased exchange diffusion across the outer fibre membrane because similar A23187induced augmentations of 45Ca outflux were recorded in experiments with 0 Ca in the external solution. These data suggest that the intracellular calcium storage sites are involved.

This was tested by recording the rate of light emission of a barnacle fibre micro-injected with aequorin15,14. The fibre was stimulated at intervals of more than 30 s through an intracellular silver wire with square electrical pulses of 75 or 150 ms duration of various intensities. The membrane potential was monitored with another intracellular platinum electrode connected to a

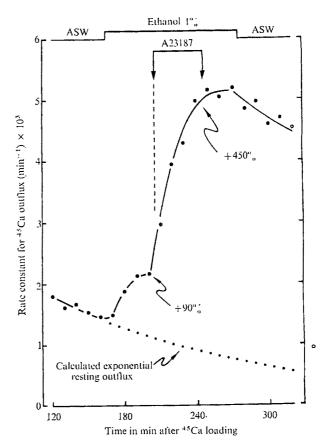

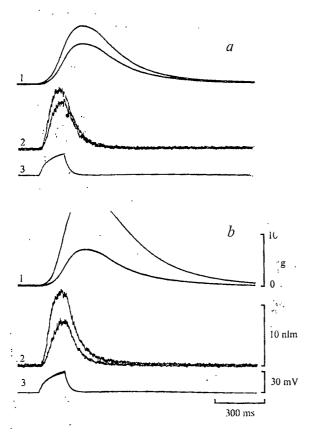

Fig. 1 Effect of A23187 10<sup>-5</sup> M on the <sup>45</sup>Ca outflux from a single barnacle muscle fibre. The exponential resting outflux curve  $(y=ae^{bx}; a=57.09 \text{ and } b=-0.01;$  coefficient of determination  $r^2=0.7831$ ) was calculated from the experimental data recorded after 2 h equilibration of the fibre in ASW. The ionophore solvent, ethanol, modified the resting outflux: 90% above baseline after 30 min. This was followed by a marked increase of the outflux (450% in 40 min) when A23187 was added to the external medium. Only a moderate recovery was observed when this fibre was transferred back to ASW. Fibre diameter: 1.0 mm; mean intracellular resting potential: -48 mV; temperature of mean intracellular resting potential: -48 mV; temperature of solutions: 22° C.

Result of applying a single electrical stimulation of 150 ms duration to a barnacle muscle fibre injected with aequorin. Two traces are superimposed in each record: one before the application of A23187 serving as control and the other after the ionophore had been present for 10 min. Trace 1, isometric tension; trace 2, calcium mediated light emission; trace 3, membrane response. The slight decrease observed in trace b,3 was recorded in presence of A23187. Fibre diameter: 1.9 mm; mean intracellular resting potential: -54 mV; temperature of solutions: 23° C. a, A23187 (10<sup>-6</sup> M); b, A23187 (10<sup>-5</sup> M).

high input impedance amplifier<sup>15,14</sup>. Figure 2 illustrates typical results obtained on the same muscle fibre in the presence of two different concentrations of A23187, under identical stimulation conditions. Two traces are superimposed in each record, one before the application of A23187 serving as control and the other after the calcium ionophore had been present in the external medium for 10 min.

The membrane depolarisations actually elicited by the constant intensity stimulus (record 3) were stable in the control and test trials which indicates that any difference in the force output (record 1) or in the calcium transient (record 2) must result from genuine changes in the mechano-chemical activation processes (compare ref. 15). No regenerative action potential was elicited by the stimuli as shown by the intracellular record 3. In the presence of 10<sup>-8</sup> M A23187 the mechanical force output (record 1) increased by 42% but it was not prolonged (Fig. 2a). The size of the calcium transient (record 2) increased by 28% in Fig. 2a and its rate of rise was much accelerated so that the peak was reached somewhat earlier. The duration of the calcium transient was not significantly prolonged and the time from peak to half decay was indeed slightly reduced. A concentration of 10<sup>-5</sup> M A23187 was tested in Fig. 2b. After 10 min the force was considerably increased to about 3 times control. The rate of force development was accelerated. The calcium transient was increased by 70%, its rate of rise was accelerated and the time from peak to half decay was about the same as that of control. These results were regularly obtained in 5 muscle fibres from 4 different barnacles, each one being tested with different combinations of stimulus parameters and of ionophore concentration from  $10^{-7}$  to  $10^{-5}$  M. The above modifications returned to

control values when the fibre was transferred to without ionophore in a time variable from 10 to 20 min.

The above results suggest that when the calciunophore A23187 10<sup>-7</sup> to 10<sup>-5</sup> M is added to the fluid bay a single giant muscle fibre, its action involves not one outer membrane (Fig. 1) but also the intracellular cal storage sites. The latter effect was very strong and a standapolarisation step imposed to the outer membrane evokearger and faster release of calcium which in turn elicited ath potentiated twitch (Fig. 2). The resting light emissivas only slightly increased when the potentiation was ided. The A23187 potentiation which occurs without alignificant prolongation of the mechano-chemical events pres a formal resemblance to the staircase potentiation3 which onsider to involve primarily the calcium release from SR. effect of A23187 has a rather rapid onset and large polations of the contraction can be recorded after only 1 or 2 m exposure to A23187. The effect is reversible and does apparently disturb the sequence of events involving calciumuestration by SR during the relaxation of the muscle fibre. records of Fig. 2 make it clear that the calcium ionophorethese concentrations provides a useful tool to manipulattracellular processes of excitation-contraction coupling skeletal muscle fibres directly.

This research has been supported by the Musco Dystrophy Associations of America Inc., the Fonds de Recherche Scientifique Médicale and the Fonds National de Recherche Scientifique. We wish to thank Professor J. E. mont (Biochemistry) for his help in obtaining A23187 anounting the samples of 45Ca. We are grateful to Sir AndreHuxley for reading the manuscript.

#### Precocious development of detoxicating enzymes following pituitary graft

In vertebrates many biologically-active enogenous compounds, (such as bilirubin, steroid hormones and the catecholamines) and an enormous range of drugs, carinogens, pesticides, industrial pollutants or their metabolitesare made more polar and excreted by conjugation with glicuronic acid1. This is the principal route of detoxication but only one mechanism for the biosynthesis of such 'glucuroniles' is known:

Table 1 En embryo-liver UDP glucuronyltransferase activity

1	

Tissue frd week White Leghorn cockerel was placed on the chorioallanthembrane of 12 d embryos, and GT activity assayed in embryo I on day 15. Results are from separate experiments. Weights of ther tissues were 1-3 times the weight of the single pituitary gland grafted.

glucuronyl Insfer by UDP glucuronyltransferase (GT) (EC 2.4.1.1) the accepting compound<sup>1</sup>.

GT occumily at very low levels in the embryo or foetus<sup>1</sup>; it reaches addevels around birth, the rate depending on substrate and cies. Because much drug toxicity and jaundice in the newn arises from this temporarily defective GT activity, thearch for factors controlling induction of the enzyme has n extensive.

GT activ can be increased in newborn2 or term-foetal liver (B. Buell and G. J. D., unpublished) by phenobarbital, and this druan induce GT in chick embryo liver in ovo3 or in culture4. Thendogenous inducers or inducing mechanisms, however, haremained unknown.

We reported the precocious increase of GT from virtually zero to adulvels in the livers of chick embryos in ovo, following the grafg of chicken pituitary gland on to the chorioallantoic merane. This observation should enable the identification of tlendogenous inducing mechanism of this major detoxicating zyme. We have found that pituitary grafts also allow premarely adult expression of one of the microsomal mixed-functi oxidases (EC 1.14.1.1.), enzymes which hydroxylate a molule before glucuronidation<sup>5</sup> and which are therefore also imptant in today's environment.

GT activitis detectable in chick embryo liver at 8 d but remains verlow until hatching at 21 d, when it increases dramatically adult levels. Because the culture of isolated liver out of the embryonic environment allows precocious induction of T<sup>7</sup>, an in ovo 'repression' of the enzyme has been postulated. e were unable to overcome this repression by varying O2 nd CO2 tensions, by incubating embryo and membranes an open dish, by hypophysectomising the embryo at 3h (ref. 8) or by injecting known hormones from mammalian frenal cortex, thyroid and pancreas.

The pituity begins to secrete in foetuses just before the emergence of the late-foetal cluster of enzymes, amongst which is GT and an injection of pituitary extract brought about the precociot appearance of xanthine oxidase in chick embryo liver10. We herefore attempted to evoke GT by injecting various compercial extracts or freshly-made homogenates of mammalian or chicken pituitary glands into the egg. Our results were iconclusive, and we decided to graft adult chicken

Pituitary gland from a 6 week cockerel was placed on chorioallantoic memirane of 12 d embryo and GT assayed1 in embryo liver on days roted. Results are of individual experiments or s.e.m. with number of experiments in parentheses. 'Adult range' for this batch of 6 week cockerels was 30-60 of above units. glands on to the chorioallantoic membrane to allow a more physiological uptake of possibly unknown factors.

Pituitaries were therefore taken from 6-8 week old hens or cockerels and grafted, one per egg, on to the chorioallantoic membrane of 12 d eggs. Other eggs received grafts of other tissues, control eggs were sham operated and all eggs were then returned to incubation. Embryo livers were examined on subsequent days. By the third day, embryo-liver GT activity had risen markedly in those eggs which had received grafts of pituitary gland; adult brain, adrenal, testis, liver and muscle grafted on to the membrane did not significantly alter the normal negligible embryo-liver levels of the enzyme (Table 1).

The rise in GT activity was time-dependent. It was not notable until day 3 after grafting and increased during days 3 and 4. It reached the adult range on day 4 (Table 2).

Activity of the mixed-function oxidase, aniline hydroxylase11, was also increased by pituitary-grafting; it rose threefold, reaching adult level. No rise was observed for either enzyme in embryo livers under 10 d old at the time of grafting and examined up to 4 d later.

One pituitary gland from the donor was placed on the chorioallantoic membrane of a 12 d embryo, and liver GT assayed1 on day 16. Results expressed as in Table 2. \*Two glands placed on membrane:

Pituitaries from 2 d-old chicks proved almost as effective as those from adults. Younger pituitaries, which were of approximately similar weight from 2 d chicks down to 8 d embryos, appeared progressively less effective except from those birds actively hatching (Table 3). Doubling the amount of embryo gland grafted evoked a marked response, however (Table 3), suggesting a threshold phenomenon.

The stimulatory effect is produced by the cephalic region of the anterior pituitary; the caudal region has negligible effect when grafted. Partly-purified preparations of hormones found in the cephalic region12 proved ineffective when applied to the membrane at various time intervals. Pituitaries from mouse and rat have so far also failed to increase embryo-liver GT, although the grafts were apparently accepted.

The cephalic region of the chick anterior pituitary gland therefore secretes a factor or factors which in the intact embryo in ovo causes precocious development of hepatic GT and aniline hydroxylase. Embryos over 9 d old are competent to respond to this factor, production of which seems enhanced by the process of hatching. The nature of the factor is now being determined and its role in the natural development of these detoxicating enzymes is being investigated.

We thank the SRC for a studentship to G.J.W., the MRC and SRC for grants, Dr T. W. Betz and Dr C. G. Scanes for valuable advice, and Eastwood Hatcheries, Fife, for supplying eggs and birds. The partly-purified hormone preparations were a gift from Dr Scanes.

## Transcription, translation and maturation of succinate dehydrogenase during cell cycle

A stepwise accumulation of individual enzyme activities is a common feature of the eukaryotic cell cycle1. Two major hypotheses consider that the temporal restriction is produced by oscillatory repression or by linear reading of genes along the chromosome<sup>2,3</sup>. Both hypotheses, in their present form, assume that increase in enzyme activity is concurrent with transcription and translation. We have made use of the high degree of synchrony obtainable with Chlorella fusca var. vacuolata 211-8p, grown under intermittent illumination<sup>4,5</sup>, to study the duration of transcription and translation for succinate dehydrogenase by applying inhibitors during the period of its stepwise increase in activity. We report that the periods of transcription, of translation and of increase in activity are only partially concurrent.

Cycloheximide specifically inhibits protein synthesis of this strain of Chlorella<sup>6</sup> and its addition at 15 h in the 24 h cycle completely prevents the stepwise accumulation of succinate dehydrogenase (Fig. 1a) which would normally begin then?. It is striking that addition of the inhibitor less than 0.1 cycles later, at 17 h, when only a third of the full increase in activity has occurred, is unable to prevent the full subsequent accumulation of enzyme activity. Measurement of phenylalanine incorporation into protein, however, shows that cycloheximide retains its ability to inhibit protein synthesis even when the increase in succinate dehydrogenase activity is immune to its presence (Fig. 1b). The inhibition of protein synthesis is not an artefact caused by loss of labelled amino acid from the cells, as whole-cell counts show retention of the pool during exposure to cycloheximide (Fig. 1c). Therefore the accumulation of succinate dehydrogenase activity rapidly enters a phase in which it is not dependent upon continued protein synthesis by the cytoplasmic ribosomes. As succinate dehydrogenase is an enzyme of the inner mitochondrial membrane8.11, however, and as much of this membrane is synthesised within the organelle11,12, we investigated the possibility that the period when enzyme activity accumulates without cytoplasmic protein synthesis is one in which proteins must be synthesised by the mitochondrial ribosomes to allow the enzyme to develop into its catalytically active form. Chloramphenicol was shown to be an effective inhibitor of mitochondrial protein synthesis during this period of the cycle because it prevented the accumulation of cytochrome oxidase (Fig. 2a), an enzyme known from very diverse sources to contain some proteins of mitochondrial  $origin^{12-14}$ . The presence of chloramphenicol from as early as 11 h was, however, not at all inhibitory to the accumulation of succinate dehydrogenase (Fig. 2b). Similarly, lincomycin at 0.2 mg ml-1 inhibited cytochrome oxidase but not succinate dehydrogenase synthesis. Therefore that period of the increase in enzyme activity after 17 h, which does not require con-

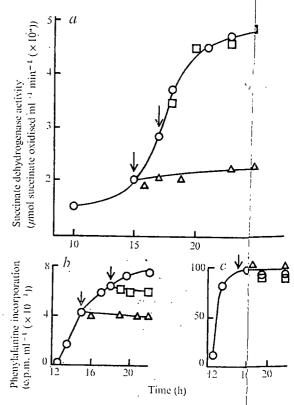

Fig. 1 The effect of cycloheximide, a, on the accilation of succinate dehydrogenase activity, b, the incoration of phenylalanine into protein and, c, the uptake of pylalanine. Cells were synchronised and held at a density of 5 × ml-1 under a regime of 15 h light and 9 h dark which wanaintained during the experimental period. Cycloheximides, $\square$ ) was applied at 2.5  $\mu g$  ml $^{-1}$  (arrows), and  $^{14}\text{C-r-}3$ -phenanine (U) was added at  $10^{-3}$  M and 25  $\mu\text{C}$  immol $^{-1}$ . The cultures sampled and assayed for succinate dehydrogenase activity described previously with the modification that for 10 min the 15 min in vitro succinate activation<sup>8</sup> period, the enzyme vincubated with 0.15 M succinate, pH 7.4, before addition the assay reagents. For estimation of phenylalanine incorpation into protein, the following procedure was necessary completely leach free phenylalanine through the sporopollenirall<sup>9,10</sup>. Five ml of culture was mixed with 15 ml of ethanol 1 stored at -15° C. The cells were pelleted, washed in cold gith medium containing  $5 \times 10^{-8}$  M cold phenylalanine and eacted with ethanol at  $80^{\circ}$  C for 3 min and ether at  $60^{\circ}$  C fd min. The protein was dissolved in 0.2 ml of 8 M urea contain;  $5 \times 10^{-3}$  M phenylalanine and 15 mg ml<sup>-1</sup> bovine serum albumind was then precipitated with cold 5% trichloroacetic acid, wasd with cold water, extracted in 0.5 M H<sub>2</sub>SO<sub>4</sub> at 100° C for h, washed briefly with hot water and dissolved in 0.1 ml of M NaOH. For counting, the alkali was neutralised with 0.ml of 1 M phosphate buffer, pH 6.8, and 0.1 ml of 10 M H(and 0.2 ml samples were mixed with 0.8 ml H<sub>2</sub>O and 10 ml scillant, which contained 50 ml Triton X-100 and 0.7 g butyl-PB per 100 ml toluene. For measurement of phenylalanine uptake mi samples of culture were passed through a membrane filternd the cells washed three times with cold growth medium the dried overnight at 105° C and counted with 3 ml of scintillai O, Control

current cytoplasmic protein synthesis (Fig. a), does not depend on mitochondrial protein synthesis either

The increase in activity cannot be attributed a change in the substrate affinity of the enzyme, for we shall how elsewhere that the  $K_m$  values for succinate and phenazinemethosulphate do not change significantly. Neither does the accessibility of the enzyme in cell extracts vary, because the mitocondrion forms a single reticulum15 which is always completed disrupted by the force necessary to break the sporopolinin-containing cell wall. Instead there seems to be a real increae in the number of catalytically active enzyme molecules betwen 17 and 24 h, due to the maturation of enzyme protein mide between 15 and 17 h.

To investigate the relationship between transription and the

2 h periodranslation we have employed 6-methylpurine. This analophibits RNA synthesis both in higher plants 18-18 and in this of Chlorella, where its effect is specifically to inhibit funal RNA synthesis by competition with adenine19. When 6-mpurine is added at 12 h the subsequent synthesis of nate dehydrogenase is completely inhibited (Fig. 3a), le is no evidence, therefore, of a persistent mRNA forenzyme throughout the cell cycle. When added at 18 h, aftenslation has ceased, the inhibitor had no effect (not showmere is, however, evidence that the newly transcribed mR is not immediately translated as, although translation does begin until 15 h (Fig. 1a), the addition of 6-methylpulto a different sample from the same culture at 15 h reveals the inhibition of RNA synthesis is only able to inhibit halfihe subsequent enzyme accumulation (Fig. 3a). Thus, aboulf of the necessary mRNA may have already been transcil at the time of initiation of translation.

This conon is only valid if 6-methylpurine is able to cause immediate bition of functional RNA synthesis: therefore its ability tompete with adenosine for incorporation into RNA was itigated at this time in the cycle. Although the analogue cotted with adenosine for uptake, there was no loss of labeladenosine from the intracellular pool (Fig. 3b) but there wan immediate 65% displacement of adenosine from incorption into RNA (Fig. 3c). Purified tritiated 6-methylpurins itself incorporated into all sizes of RNA separated by electrophoresis (C. A. Lambe and P.C.L.J., unpublished

The evide obtained by use of 6-methylpurine therefore suggests theesence of some mRNA for succinate dehydrogenase beforanslation begins. Yet there is no evidence of mRNA befol 2 h in the cycle (Fig. 3a) and so the maximum period durin/hich mRNA may be present, before translation begins at 15 is less than 0.15 cycles. Therefore, the time of succinate delrogenase synthesis is closely determined by the time of transportion. This is the first time that transcription has been shot to have a role in determining the time of syn-

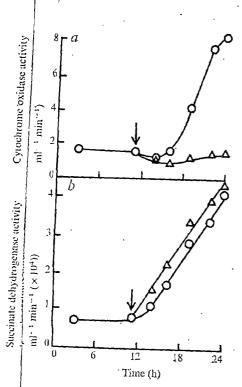

Fig. 2 The effect of chloramphenicol on, a, the synthesis of cytochrome bxidase and, b, succinate dehydrogenase. D-threo-chloramphenicol ( $\triangle$ ) was applied at 0.8 mg per ml at the times arrowed, and the cells were cultured as in Fig. 1. The culture was sampled and assayed for cytochrome oxidase as described previously and for succinate dehydrogenase as in Fig. 1. O, Control curve,

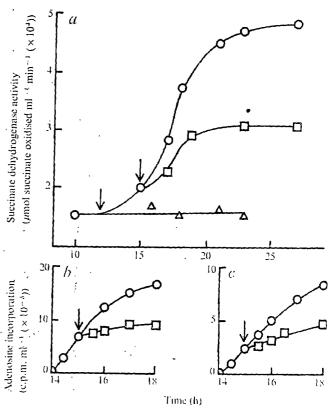

Fig. 3 The effect of 6-methylpurine on, a, the synthesis of succinate dehydrogenase, b, the uptake of adenosine and, c, the incorporation of adenosine into nucleic acid. The cells were grown as described in Fig. 1 and 6-methylpurine (Δ, ) was added (arrows) at 1×10<sup>-8</sup> M. <sup>14</sup>C-adenosine (U) was supplied at 1.25×10<sup>-6</sup> M and 26 mCi mmol<sup>-1</sup>. For measurement of total cellular uptake, 5 ml of culture was filtered through a double thickness of Whatman GF/A glass fibre filter and washed twice with cold growth medium containing 1.25×10<sup>-6</sup> M cold adenosine, then dried at 75° C overnight and covered with scintillant as in Fig. 1. For estimation of adenosine incorporation into nucleic acid, 5 ml samples of culture were made up to 5% perchloric acid and stored at 0° C. The cells were filtered, washed with 5% cold perchloric acid dried at 105° C and counted in the same way. O, Control curve.

thesis of a stepwise accumulated enzyme and there are few other investigations of the role of transcription in determining any pattern of synthesis in the cell cycle. In the thermophilic strain of *Chlorella* the glutamine analogue azaserine immediately inhibits synthesis of two autoregulated enzymes <sup>20,21</sup> and 6-methylpurine prevents the increase in glucose-6-phosphate dehydrogenase activity which occurs in excised artichoke tissue<sup>18</sup>.

There is therefore some support for the conclusion that transcriptional regulation can govern the pattern of enzyme synthesis in the cell cycle, but the delay observed here before translation of the mRNA might indicate that post-transcriptional regulation also operates. Control at this level is believed to govern isocitrate lyase synthesis under catabolite repression22 and nitrate reductase synthesis under ammonia repression<sup>5</sup> in this strain of Chlorella. Post-transcriptional controls may also be involved in the synthesis of tyrosine aminotransferase in hepatoma cells 23,24 and in the synthesis of some proteins 25-27 in other developmental situations analogous28 to progress through the cell cycle. At least some of the pre-formed mRNA, however, will be mRNA undergoing the normal procedure of processing and export from the nucleus. We therefore believe that the period when mRNA for succinate dehydrogenase is available in the cytoplasm but remains untranslated, can only be brief in relation to the cell cycle.

The enzyme is not matured into a catalytically active form before incorporation into the mitochondrial membrane, as no significant activity can be detected in the soluble fraction,

after centrifugation for 30 min at 100,000g, at any time during the phase of increasing activity. This raises the possibility that the maturation process depends on the rate-limiting synthesis of new inner mitochondrial membrane to accommodate the enzyme. In fact, a burst of mitochondrial membrane synthesis at just this stage of the cycle, after S phase, is predicted by a recent hypothesis 29,30.

Stereology has revealed that there is a continuous increase in mitochondrial volume during the cycle5.15, and furthermore we have found that the presence of chloramphenicol from 11 h in the cycle, which would be expected to block inner membrane synthesis 11,12,14, still allows the formation of fully particulate enzyme. Maturation is thus not limited by the availability of membrane to accommodate the new enzyme. Another factor, perhaps the rate of incorporation into the membrane or the addition of the flavin prosthetic group8, must determine the rate at which catalytic activity develops.

We conclude that the stepwise synthesis of succinate dehydrogenase is initiated by a brief period of transcription which begins perceptibly before the 2 h period of translation; however, enzyme activity accumulates for a total of 9 h because there is a further, rate-limiting, step in the formation of active; membrane-bound enzyme.

#### Feedback control of vitamin D metabolism by a nuclear action of 1,25-dihydroxycholecalciferol on thidney

1,25-DIHYDROXYCHOLECALCIFEROL (1,25 DHCC the most active metabolite of vitamin D<sub>3</sub><sup>1-4</sup>, and its productiothe kidney in vivo varies with the calcium and vitamin D ent of the diet<sup>5</sup>. In spite of several theories, the mechani by which dietary changes cause alterations in 1,25 DH6roduction are not completely understood. Hormonal<sup>6-8</sup>1 ionic<sup>9-11</sup> messengers have been suggested, and both maive a role.

In a previous report<sup>10</sup>, we described inhibition he conversion of 25-hydroxycholecalciferol (25 HCC) t25 DHCC in vitro after incubation of isolated chick kidnabules with 1,25 DHCC. We show here that this inhibition of due to a direct competitive effect of 1,25 DHCC, but that probably due to an action on the nucleus. Because of a depence of this effect on the calcium ion concentration, and by agy with the mode of action of 1,25 DHCC in the intestine, it ioposed that 1,25 DHCC induces the formation of proteins alved in calcium movement into and across the cell. The km sensitivity of the 25 HCC-1-hydroxylase enzyme to calcium uggests that this enhanced calcium entry into the cell may eain the inhibitory effect of 1,25 DHCC on the 25 HC(hydroxylase enzyme. The proposed mechanism would exm the interdependence of 25 HCC-1-hydroxylase activity, the calcium and vitamin D nutritional state observed in vivo

Table 1 Effect of preincubation with 1,25 DHCC (5 nmol 1<sup>-1</sup> in (a) and 25 nml 1<sup>-1</sup> in (b)) for (a) different time intals, and at (b) different calcium concentrations on the conversion of6-(27)-methyl-3H)-25 DHCC to 1,25 DHCC by isolated renal tubu from vitamin D-deficient chicks

The tubules were preincubated for 6 h in mea with different calcium concentrations. The tritiated 25 HCC waladded after the preincubation period and the conversion to 1,25DHCC assessed 15 min later. 1,25 DHCC was added in 5 µl ethanl, and an equal volume of ethanol was added to tubes not containing 1,25 DHCC. Incubation, extraction, separation and counting is the radioactive metabolites were performed as described previous, 10 except that an incubation volume of 1.5 ml was used. It is imporant to note that the tubules remained biochemically viable for at least 6 h, as assessed by ATP levels after different periods of incubation (15 min, 1.91 µg mg<sup>-1</sup> protein; 1 h 2.09 µg mg<sup>-1</sup>; 3 h, 1.44 µg mg<sup>-1</sup> 6 h, 1.68 µg mg<sup>-1</sup>) and <sup>14</sup>CO<sub>2</sub> production from [U-<sup>14</sup>C] glucose whichwas linear for 8 h. Statistical comparisons were made by the unpaired Student's t test.

\* Not significent \* Not significant.

Competinhibition was eliminated in several ways. There is a lag between exposure of the tubules to 1,25 DHCC arhibition of 25 HCC-1-hydroxylase activity (Table 1a) his and other experiments it was found that a minimum omin preincubation in 1,25 DHCC was necessary before inhon of 25 HCC-1-hydroxylase activity was apparent. Time lag was not due to delay in entry of 1,25 DHCC inte cell, as in broken cell preparations (homogenates), 1)HCC in concentrations up to 125 nmol 1-1 (50 ng ml-1 no acute effect on 25 HCC-1-hydroxylase activity (outublished observations). Finally, as seen in Fig. 1, the possibilit the observed inhibition being competitive in type was cetely eliminated by showing that the effect of 25 nmol 1-1 25 DHCC on the rate of the reaction was not reduced by asing the substrate concentration from 12.5 to 150 nmol 1

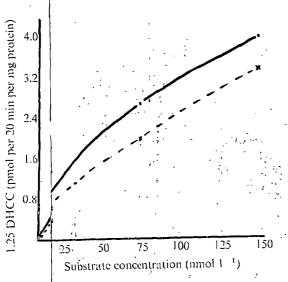

Fig. 1 Relianship between substrate concentration and the rate of the hversion of 25 HCC to 1,25 DHCC in isolated chick renal jules. —, after 6 h preincubation in buffer and —, after h preincubation in buffer containing 25 nmoll<sup>-1</sup> of 1,25 DHC. In the presence of 1,25 DHCC, the rate of the conversion is reduced at each substrate concentration. In This experient, biosynthetically prepared 1,25 DHCC was used (prepar and donated by Dr E. B. Mawer, Department of Medicine, Uversity of Manchester), and its purity was checked by high spe liquid chromatography (E. W. Matthews et al. unpublished).

The possibly that the time lag in onset of the inhibitory effect of 1,25 HCC was due to a nuclear interaction with the renal cell respisible for the 25 HCC-1-hydroxylase activity was investigated studying the effect of actinomycin D. This antibiotic is relatively specific inhibitor of DNA-directed RNA transcrition<sup>12,13</sup>. The concentration used (5.4 µmol l<sup>-1</sup>) inhibited 97 of 5-3H-uridine incorporation into acidprecipitable INA after 30 min exposure of the tubule cells. Exposure to a inomycin D for 6 h did not increase 1,25 DHCC production, ht it did abolish the inhibitory effect of exposure of te tubules to 1,25 DHCC for 5.5 h (Table 2). Although exprience has taught caution in the interpretation of the results of periments using inhibitors of RNA or protein synthesis, the acts that basal 25 HCC-1-hydroxylase activity was not reduced, and 14CO2 production from [U-14C] glucose is not affected, aggest that actinomycin D was not acting as a non-specific toin. The results support the concept that the inhibitory effect of 1,25 DHCC on its own formation might be mediated by a luclear effect of this steroid hormone in initiating new RNA transcription.

A nuclear effect of 1,25 DHCC could not lead to inhibition of 25 HCC-1-hydoxylase activity by preventing the formation of the messenger RNA for the 25 HCC-1-hydroxylase enzyme, because virtualy complete interruption of all new RNA formation by actiomycin D did not depress the enzyme activity.

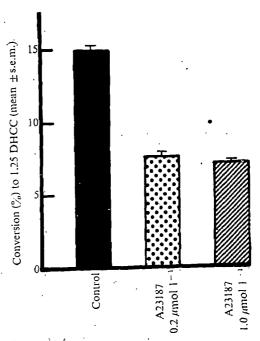

Fig. 2 Effect of the calcium ionophore A23187 on the conversion of 25 HCC to 1,25 DHCC. The preparation was preincubated for 15 min before the addition of tritiated 25 HCC and a further 15 min incubation. Cellular respiration, as assessed by <sup>14</sup>CO<sub>2</sub> production from [U-<sup>14</sup>C]glucose, was unaffected by the ionophore.

The most likely explanation is that, as in the intestine<sup>14,15</sup>, 1,25 DHCC increased the synthesis of proteins concerned with calcium transport<sup>16</sup>. This could result in inhibition of the 1-hydroxylase enzyme, which is known to be sensitive to calcium ion *in vitro*<sup>8,9</sup>. The demonstration of a vitamin D-dependent calcium-binding protein in the kidney is consistent with this view<sup>17</sup>.

The possibility that calcium ion influx could account for inhibition of 25 HCC-1-hydroxylase activity in intact cells was tested by studying the effect of the ionophore A23187<sup>18</sup>. This agent forms lipophilic complexes with calcium (and magnesium) ions, allowing their rapid entry into cells. This agent markedly inhibited 25 HCC-1-hydroxylase activity (Fig. 2), presumably by promoting calcium ion entry. Finally, the experiment shown in Table 1 (b) demonstrated that the inhibitory action of 1,25 DHCC was abolished by lowering the extracellular calcium ion concentration of the medium.

Figure 3 summarises the scheme proposed for regulation of 25 HCC-1-hydroxylase activity at the cellular level. Reabsorption of the calcium from the tubular lumen is enhanced by 1,25 DHCC, presumably by its effect on the synthesis of proteins involved in calcium transport. However, if the calcium concentration in the tubular lumen at the site critical for the hydroxylation of 25 HCC is low, 1,25 DHCC production is unaffected. But if the renal tubular calcium rises, sufficient calcium may be reabsorbed to suppress 1,25 DHCC production. This effect on

Table 2 Prevention by actinomycin D of the effect of 1,25 DHCC on conversion of 25 HCC to 1,25 DHCC in chick kidney tubules

CONVENSION OF 25 THE CONT		Significance

1,25 DHCC (25 nmol 1 <sup>-1</sup> )		

Actinomycin D was added 30 min before 1,25 DHCC; there was a further 5.5 h preincubation prior to the addition of tritiated 25 HCC. In addition actinomycin D (5.4  $\mu$ mol l<sup>-1</sup>) does not impair  $^{13}$ CO<sub>2</sub> production from [U- $^{14}$ C] glucose by the tubules at 3 h or 6 h incubation (unpublished results).

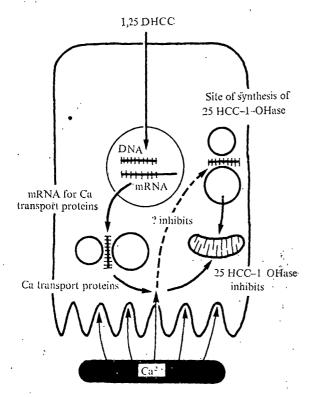

Fig. 3 Schematic representation of a renal tubule cell showing proposed action of 1,25 DHCC on reabsorption of calcium and 25 HCC-1-hydroxylase activity. Other actions of 1,25 DHCC on the tubule cell, such as induction of another hydroxylase enzyme, 25 HCC-24-hydroxylase, are also possible, but are not shown as our in vitro experiments gave no direct evidence for them. Similarly an effect at the translational level may exist and is indicated by

enzyme activity could be followed by a delayed action on enzyme synthesis. In the absence of 1,25 DHCC, it would be predicted that only very high plasma and urinary calcium concentrations could inhibit 25 HCC-1-hydroxylase activity. This is consistent with in vivo observations<sup>5</sup>.

Thus it is proposed that 1,25 DHCC has a dual role in the kidney. It enhances calcium conservation by increased synthesis of calcium transport proteins and, perhaps more importantly, it allows the renal cell responsible for the production of 1,25 DHCC to respond appropriately to normal or high urinary calcium concentrations by reducing the rate of formation of 1,25 DHCC.

These experiments, and the hypothesis they have led to, do not imply that other control mechanisms do not exist. It has become apparent that the regulation of 1,25 DHCC production has multifactorial control, as have most other endocrine systems, and hormonal factors may also be important. The results do however, suggest a teleological explanation for the siting of the 25 HCC-1-hydroxylase enzyme system in the kidney tubule, where it is able to sense and respond to fluctuations in calcium concentration in the main outflow site from the extracellular compartment, and to circulating 1,25 DHCC concentrations.

We thank Professor Sir Derek Barton and Dr Maurice H. Pechet for synthetic 1,25 DHCC and Dr E. B. Mawer for biosynthetic 1,25 DHCC. The Lilly Research Centre Ltd, Windlesham, Surrey, kindly provided the ionophore A23187, and Dr A. Kissebah performed the ATP estimations. This work was supported in part by grants from the Medical Research-Council and the Wellcome Trust.

#### Erroneous base-pairing induced by chemical carcinogen during DNA sthesis

The stability of binding of chemical carcinoge to DNA1-5 in vivo suggests a molecular mechanism for turn initiation. This interaction may be mutagenic in that it ay affect the accuracy with which the modified DNA is cord by cellular DNA polymerases. We now report that the mification of a synthetic polynucleotide template with  $\beta$ -propiolone increases

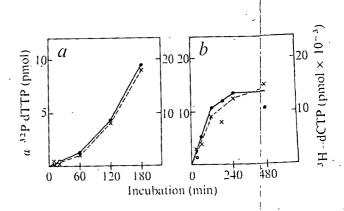

Fig. 1 Time dependency of complemental and non-complementary nucleotide incorporation. a, AMV DNA polymerase, 1 μg of 85 μM modified poly(dA) ligo(dT) was incubated at 37°C in a mixture containing equal quantities of complementary and non-complementary nucleotide concentrations. b, Sea urchin nuclear DNA poymerase, 1 µg of 43 µM modified template was usd.

The assays for simultaneous incorporation of omplementary and non-complementary nucleotides are deailed in the legends to Tables 1 and 3. •, Complementary nucleotide incorporation; x, non-complementary nucleotid incorporation.

Modification of poly(dA) oligo(dT) template	Complementary nucleotide (dTTP) incorporation (pmol)	Non-complementary nucleotide (dCTP) incorporation (pmol)	Error rate
No BPL	6.95	0.012	1/579
9 µM BPL	5.12	0.012	1/426
43 µM BPL	4.96	0.023	1/215
85 µM BPL	5.50	0.027	1/203

The incorion of complementary (dTTP) and non-complementary (dCTP) nucleotides by AMV DNA polymerase was measured at 37° C for 60 min. Taction mixtures (total volume 0.05 ml) contained 50 mM Tris-HCl (pH 8.0), 5 mM MgCl<sub>2</sub>, 20 mM KCl, 5 mM dithiothreitol, 2 µg bovine albumin, 26 µM α-32P-dTTP (20 d.p.m. pmol<sup>-1</sup>), 30 µM 3H-dCTP (55,000 d.p.m. pmol<sup>-1</sup>), 0.1 mg of AMV DNA polymerase, and I ug of ned or unmodified poly(dA) oligo(dT). Samples were washed as previously described14. The values given represent the average of triplicate minations. The error rates were determined by simultaneous incorporation of dTTP and dCTP and varied by less than 10%.

the incorpon of non-complementary base-paired nucleotides into I with the DNA polymerase from either avian myeloblastovirus (AMV) or sea urchin embryos. Homogeneous AIDNA polymerase and partially purified sea

The compil reaction mixtures and incubation conditions are given in Tabl 1 and 3. The absolute error rates of AMV DNA polymerase area urchin DNA polymerase should not be compared because partily purified sea urchin enzyme was used in these studies.

urchin nucleaDNA polymerase, which are devoid of nuclease activity<sup>6,7</sup> we used. β-Propiolactone is a potent mutagen<sup>8,9</sup> and carcinon, initiating tumours in mice10, rats11 and hamsters12. Is an alkylating agent that reacts with guanine and adenine icleotides in DNA13.

β-Propiolapne (0-85 μM final concentration) was incubated with 200  $\mu$ g f poly(dA) $\frac{1}{2000}$  oligo(dT)<sub>12-18</sub>, mass ratio 1:1, for 20h at 3 C in the dark. Unbound  $\beta$ -propiolactone was removed by dlysis for 24h at room temperature. Studies with 3H-β-propiolitone (Searle, Amersham) demonstrate that at a final concentration of 43 µM one molecule was bound per 180 nucleotide residues in the template. All radioactivity after dialysis was acid-precipitable. As a control, poly(dA)2000 oligo(dT)<sub>12-18</sub> was incubated without β-propiolactone; and the modified and unmodified poly(dA)<sub>2000</sub>·oligo(dT)<sub>12-18</sub> were dialysed together. Size distributions of the unmodified and carcinogen-modified templates were similar as determined by zonal sedimentation in neutral sucrose gradients.

The accuracy of DNA synthesis with AMV DNA polymerase and modified poly(dA)<sub>2000</sub>·oligo(dT)<sub>12-18</sub> was determined (Table 1). Synthesis was measured by the simultaneous incorporation of the complementary ( $\alpha$ -32P-dTTP) and non-complementary (3H-dCTP) nucleotides. As previously reported, AMV DNA polymerase incorporates an unusually large number of non-complementary nucleotides14. With  $poly(dA)_{2000} \cdot oligo(dT)_{12-18}$  as a template, AMV DNA polymerase incorporates one molecule of non-complementary nucleotide (dCTP) for approximately every 600 molecules of complementary nucleotide polymerised. We found that the number of non-complementary nucleotides incorporated increased progressively as template modification was increased. This error rate of 1/579 increased to 1/203 as a result of treatment with β-propiolactone. Modification with increasing amounts of  $\beta$ -propiolactone did not significantly decrease the incorporation of complementary nucleotides. Although the absolute error rates varied as much as twofold in experiments with different preparations of enzyme, a relative increase in error rates with carcinogen treatment similar to that shown in Table 1 was observed in all experiments.

The reaction requirements for the incorporation of noncomplementary nucleotides with carcinogen-modified templates are shown in Table 2. The incorporation of non-complementary nucleotides was totally dependent on Mg2+, correct nucleotide (dTTP), enzyme and template. Elimination of any of these components eliminated detectable incorporation of noncomplementary nucleotide. These requirements are similar to those reported for unmodified templates14 and suggest that polymerisation is required for the incorporation

Table 3 Response of sea urchin nuclear DNA polymerase to carcinogen-modified poly(dA)·oligo(dT)						
Modification of poly(dA) oligo(dT) template	Complementary nucleotide (dTTP) incorporation (pmol)	Non-complementary nucleotide (dCTP) incorporation (pmol)	Error rate			
No BPL 9 µM BPL 43 µM BPL 85 µM BPL	37.36 56.31 33.68 17.89	0.0097 0.023 0.016 0.011	1/3852 1/2448 1/2105 1/1626			

Complementary (dTTP) and non-complementary (dCTP) nucleotide incorporation by sea urchin nuclear DNA polymerase was measured at 28° C for 8 h The reaction mixture (0.05 ml total volume) contained 40 mM Tris-HCl (pH 8.0), 4 mM MgCl<sub>2</sub>, 6 mM dithiothreitol, 50 mM  $\alpha$ -32P-dTTP (38d.p.m. pmol<sup>-1</sup>), 50 mM <sup>3</sup>H-dCTP (2.74×10<sup>3</sup> d.p.m. pmol<sup>-1</sup>), 10% glycerol, 3 µg sea urchin nuclear DNA polymerase, and 1.5 µg of modified or unmodified poly(dA) · oligo(dT). Samples were washed according to the procedure of Battula and Loeb<sup>14</sup>. The enzyme used in this experiment corresponds to Fraction V as previously reported<sup>15</sup>.

non-complementary nucleotides. The time dependency of non-complementary nucleotide incorporation was also investigated (Fig. 1a). There was coordinate incorporation of non-complementary and complementary nucleotides, suggesting that these errors are evenly distributed during synthesis. The product of the reaction was digested by snake venom phosphodiesterase. Chromatographic analysis demonstrated that the 3H and 32P radioactivity in the product was recovered as <sup>3</sup>H-cCMP and <sup>32</sup>P-dTMP. This indicates that the <sup>3</sup>H count in the product is indeed dCMP and that the non-complementary nucleotide is present in phosphodiester linkage.

To test whether this increase in errors in DNA synthesis was unique to AMV DNA polymerase, we also used sea urchin nuclear DNA polymerase. As Table 3 shows, the error rate with unmodified poly(dA) oligo(dT)<sub>12-18</sub> was 1/3852 and could be increased to 1/1626 with more extensive template modification. When the template was treated with the carcinogen there was an initial stimulation in synthesis followed by a decrease in synthesis as template modification increased. The incorporation of the non-complementary nucleotide was dependent on Mg2+, correct nucleotide, enzyme and template (Table 3). The time dependency of the reaction (Fig. 1b) shows that continued synthesis is required for incorporation.

These results demonstrate a possible relationship between a chemical carcinogen and errors in DNA replication. The accuracy with which a polynucleotide template is copied by AMV DNA polymerase and by sea urchin DNA polymerase is decreased as a result of modification of the template by the carcinogen. Even though the stoichiometry of bound β-propiolactone approximates the increased number of errors observed with AMV DNA polymerase, we have no direct evidence that the alkylated nucleotides are in juxtaposition to the observed errors in the newly synthesised DNA. Thus, a chemical carcinogen may potentiate the mutagenic effects of the AMV DNA polymerase and may directly induce mutations during DNA replication in normal cells.

#### Early simultaneous appearance of antigen binding cells in the foetal she

THE two classes of theory on the generation of diy in the immune system differ as to when the genetic capfor producing a full repertoire of antibody clonotypes is ved. The germline theory proposes that diversification occainly on an evolutionary timescale at the species level, withimmune capacity of an individual predetermined at tistant of fertilisation; the various somatic theories2-8 pro a much briefer period of diversification from a minimal cement of V genes, occurring during the ontogeny of the idual or even later in life. We have attempted to study the course of generation of diversity by following the appearancymphoid cell receptors binding any of several antigens in fisheep.

If one assumes that cell-surface receptors for en reflect accurately the antibody specificities produced by ells, then, according to the germ-line theory, one predictioned be that all receptor specificities should arise simultaneous soon as the immune system had developed to the powhere the receptors could be displayed on the surfaces of hoid cells. According to somatic theories, the appearand various receptor specificities might follow several diffe patterns. (a) If diversification occurred randomly, then in ane animal there should be a random accumulation of receptecificities following no set time course, except for the earlyression of certain high probability 'hot-spot' mutations or gic changes few steps removed from the original, small gerne set of Vgenes. (b) If diversification were antigen driven, the number of receptor specificities and the frequency of aen-binding cells (ABC) for related antigens should increasith antigen exposure. (c) Another possibility would be primitive antigen receptors, which bind weakly to a la variety of antigens, would be replaced, as genetic diversifica occurred, by receptors which would discriminate much te precisely among different epitopes.

Silverstein has reported that the maturaticof immune competence in the foetal sheep, as measured bhe animal's ability to make antibody, does not occur at thene stage of development for all antigens, but follows a partier sequence: anti- $\Phi X174$  antibody can be made at day 35 gestation, anti-ferritin at day 65, anti-ovalbumin at day i, and antibodies to Salmonella and BCG only several we after birth (where full term is about 150 d). A hierarchy of ponsiveness to nine bacteriophage, hapten and protein anths has also been described in the opossum<sup>10</sup>. The stage of elopment is quite different, however, at which the opossum st responds to two antigens also used in the sheep studic The events leading up to antibody synthesis include the interion of T and B lymphocytes and macrophages; therefore, a la of response could be due to a deficiency of receptor-geneing cells or

essential accessory cells9.

We chose to look for cells capable of specially binding antigen, among which population the precursorof antibodyforming cells and T helper cells would be expecte to be found, to see how early in ontogeny such cells were resent in the foetal sheep and whether their appearance aralleled the appearance of response capacity measured by amody production. It has already been demonstrated that this heep has a proportion of Ig-bearing lymphocytes in its peripiral lymphoid organs similar to that in the mouse11, and we lve confirmed this with our fluorescent anti-sheep Ig reagent. Ince the sheep has a placental barrier to maternal immunglobulin9, the appearance of foetal antigen-binding cells ABC) should reflect the genetic capacity of the foetus to make specific antigen recognition units. Single cell suspensionswere prepared from the lymphoid organs of foetuses from tim-bred sheep at 58, 87, and 140 d gestation, and from the spleer of two of the ewes. The cells were fixed with glutaraldehyde to preserve their receptors<sup>12-14</sup>, incubated with 500 µg ml<sup>-1</sup> fluorchrome-conjugated antigen, and observed for ABC with a leitz Ortholux

fluorescericroscope equipped with Ploem-type vertical illuminatiFor a more detailed presentation of the methods, see DeLual. (submitted for publication)).

Table is the % ABC observed in the spleens of the foetal andt (pregnant) sheep. ABC were observed for all four antigs early as day 58 of gestation, including ovalbumin forh no antibody formation can be detected until 125 d ges. Splenic ABC were always Ig-bearing cells; this was examined in a 140-d foetal sheep and its dramatic increase in ABC is seen as the foetus des. ABC frequencies are higher in the adult spleen (eally in the 140-d pregnant ewe), perhaps as a respf exposure to cross-reacting antigens, a change in cell types constituting the spleen, or changes associated pregnancy as observed in the mouse<sup>16</sup>. Binding of HSF, and GZ were shown to be non-competitive by inhibition riments in which a 10-fold excess of HSF or a 40-fold exof OA prevented the binding of rhodamine-HSF or fluoresc)A, respectively, but not the binding of fluorescein-GZ. Fescein-HSF and rhodamine-HSF gave the same frequency BC with adult spleen cells.

ABC for and HSF were observed in the thymus, marrow and liver all as the spleen of the 58-d foetal sheep (Table 2). Two diffens from ABC frequencies in foetal mice16 are readily appt. First, the ABC frequency in the foetal sheep liver is verw, and many ABC are present in the marrow; even late instation, foetal mice have 0.1-0.5% ABC in the liver and vally no cells in the marrow. Foetal sheep liver contains my large hepatocytes at 58 d, contrasted to foetal

li 58 d pregnt. ¶ 140 d preant.

Cell prepanions, antigen incubation, and washes were done in buffered balaed salt solution, pH 7.2, containing 0.25% gelatin. Cells were fix with 0.2% glutaraldehyde in 0.1 M phosphate buffer pH 7.0 for min; antigen incubation was for 30-60 min. All procedures we carried out in the cold. The sheep were obtained

from Weern Scientific Breeders, Inc., Davis, California.

mouse liver hich contains mostly haematopoetic stem cells. The second evelopmental difference is in the thymus. Mice have high AC frequencies (of the order of 1%) when the thymus can rst be studied (14 d = 70% term), declining to 0.1% by late estation and birth. At 58 d (40% term), 20 d after thymocytes 1st are observed in the thymic rudiment17, the thymic ABC requency in the foetal sheep is quite low. It may be that a decine in ABC frequency similar to that observed in mouse and human foetal thymus 16,18,19 has already occurred by 58 d gestation in the sheep.

The data presented above suggest that the inability of the foetal sheep to make an antibody response to all antigens early in development is probably a result of a deficiency in antigen handling or cell interactions, a requirement which may be more stringent for some responses than others, rather than to a lack

of B or T lymphocytes which can recognise antigen. No evidence exists for a sequential appearance of ABC for different antigens; although foetal sheep first respond to HSF at day 65 of gestation and to OA at day 125, ABC for both antigens are present on day 58. In these early ABC, the inhibition of specific antigen binding by nonlabelled homologous antigen and its absence of effect on the binding of unrelated antigens is not compatible with the concept of a primitive receptor, capable of binding many different epitopes.

Table 2 ABC in several lymphoid organs of 58 d foetal sheep %ABC\* GΖ HSF Organ 0.09 0.05 Thymus 0.60 1.0 Marrow 0.08 0.14 Spleen 0.009 < 0.02

\* At least 10 ABC or 10,000 total cells were counted for most samples.

The early appearance of ABC for a variety of antigens in mice and man16,18,19, as well as the sheep, argues against a requirement for a long period of somatic diversification to produce most of the receptor clonotypes the individual possesses. It is possible that the use of three large antigens might exaggerate the proportion of the receptor universe present at the earliest time. But our studies reported here with ovalbumin, and experiments with early foetal binding of horse radish peroxidase16 and flagellin18 seem to vitiate this objection.

We conclude that the ability to bind antigen is one of the earliest events in immune development, and that the genetic potential to respond to a wide variety of epitopes is predominantly germline in nature. The apparently orderly development of the capacity to respond to different antigens by antibody production must reflect a biological clock which modulates T cell-B cell-macrophage interactions and not the regulated acquisition of particular V-gene regions.

#### Presence of J chain in human immunocytes containing various immunoglobulin classes

THE polypeptide J chain is common to dimeric IgA and polymeric IgM<sup>1-3</sup>. Immunocytes producing such immunoglobulins have been shown to synthesise J chain<sup>4-8</sup>; its incorporation has therefore been assumed to be an essential step in the intracellular joining of the monomer (H2L2) subunits. But the finding of a monoclonal polymeric IgM lacking J chain<sup>7,8</sup>, and reassociation of IgM subunits depleted of J chain<sup>8</sup>, have led to questioning of its role as an initiator of polymerisation. Experiments demonstrating J chain in four murine IgG myeloma cell lines10 prompted me to examine its cellular localisation in human biopsy material. Cytoplasmic J chain was detected in IgD, IgM, IgG, and IgA immunocytes by direct immunofluorescence. This localisation was compared with the cytoplasmic ability to bind "secretory component" (SC) in vitro in a SC-affinity test that has been postulated to distinguish between polymer and monomer producing cells<sup>11</sup>.

Human J chain was purified from dimeric IgA by reduction with 10-20 mM dithiothreitol, gel filtration and immunoadsorption with an insolubilised antiserum to human serum12. Four rabbits each received subcutaneous injections of 0.4 mg J chain coupled to bovine serum albumin (BSA)13 and emulsified in Freund's complete adjuvant. The same dose was given after 4 weeks; and 1 month thereafter 1 mg uncoupled J chain was injected. All rabbits had an appreciable antibody titre 14 d subsequently. After adsorption with BSA and insolubilised serum from a patient with hypo-y-globulinaemia, the antisera were shown to be monospecific to J chain, giving an identity reaction with reference antiserum provided by Dr J. Mestecky. IgG from the most potent antiserum was labelled with fluorescein isothiocyanate, and a fraction of this 'green' conjugate with an absorbance ratio of 2.2 was used at 0.6 mg and 1/10 precipitating units per ml (ref. 14). Human tissue specimens were extracted for 48 h at 4° C in isotonic phosphate-buffered saline, fixed in 95% alcohol, and embedded in paraffin<sup>15</sup>. Serial sections were incubated with a combination of the 'green' anti-J-chain and a 'red' (rhodamine) conjugate monospecific to human IgG, IgA, IgM or IgD14.15. Other sections were first incubated with SC, and thereafter with a combination of 'red' anti-SC and 'green' anti-Ig to identify cells with cytoplasmic affinity for SC11,16. The sections were examined in a Leitz Ortholux microscope equipped with a Ploem-type vertical illuminator and interference filters for narrow-band excitation and selective filtration of green or red fluorescence<sup>15</sup>.

The SC affinity test distinguished between three types of tissue with regard to IgA cells: (1) immunocytes associated with glands in colon and nasal mucosa were generally positive11;

(2) tonsils contained chiefly negative IgA immunorut also positive cells scattered or in groups11; and (3) cells in inflammatory infiltrates did not generally bind Se most 'pure' cell population of the latter type was in the gingiva which is a part of the oral mucosa complacking glands. This tissue is prone to chronic inflammaticause of contact with the bacterial plaque on the teeth. Inmunocytes associated with glands, also bound SC, whthe few such cells present in the gingiva were equallitive or negative. We interpreted these findings as inng that IgA and IgM immunocytes of glandular areas predimeric or polymeric immunoglobulins containing Jh. This assumption was based on the fact that isolateneric or polymeric IgA and 19S IgM combine spontally with SC in test tube experiments; but apparently othen the immunoglobulins contain J chain<sup>8,16</sup>. Monomocluding 7S IgA, do not combine with SC. By inference rigA cells in the gingiva should produce monomeric IgA.

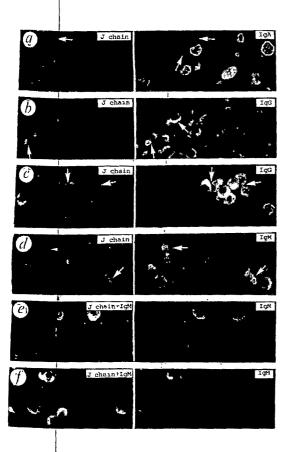

These conclusions were supported by the dimmunohistochemical demonstration of J chain. In the ga only a few (3-8) out of many IgA cells in each section fined this peptide (Fig. 1a), a number comparable with that t-binding cells. J chain could moreover be detected in onlout 50% of the few gingival IgM immunocytes. This casts with glandular areas in the nasal mucosa and colorere most IgM (Fig. 1d) and IgA cells were positive. The irity of the IgA cells was generally weak and varied considers however, possibly reflecting different concentrations of peptide (Fig. 1e). In the tonsils small groups of cellsitaining J chain especially beneath the epithelium, correspond to areas where some SC-binding IgA immunocytes were ent. These results substantiated that IgA cells appearing inflamed gingiva and tonsils are chiefly monomer proers which cannot synthesise J chain.

Many IgG cells characteristically appear in fof chronic inflammation such as in the gingiva<sup>17,18</sup> and aw (<1%) definitely contained J chain (Fig. 1b). In the supcial stroma of nasal mucosa IgG immunocytes accumulate a result of rhinitis<sup>19</sup>; 30-60% of these cells were J chain pucers (Fig. 1c). Also many of the few IgG immunocytes agent to the crypts in normal colon mucosa were J chain-litive. This was also true for IgG cells found along withM cells in some of the lymphoid follicles in the tonsils. But, two out of the four specimens (one pharyngeal and one latine) the number of positive cells was too large to be accited for by IgM, IgG and IgA immunocytes (Fig. 1f). In the two specimens cells containing IgD outnumbered thoswith IgM, especially between the lymphoid foilicles and thurface; and the majority of the IgD immunocytes were ind J chain-

The specificity of the J chain immunofluccence was established as follows: (1) Addition to the conjute of highly purified J chain (1 mg ml-1) blocked the stang reaction completely; (2) addition of comparable amount of F(ab')2 had no effect; (3) the simultaneous demonstration of J chain positive and negative immunocytes of each Ig iss excluded the possibility of cross reactions with parts of the or H chains. Furthermore, none of our conjugates produced filrescing cells when applied in working dilutions to section of a nasal polyp from a patient with hypo-γ-globulinaemia

We have thus for the first time provided eviden that J chain may be produced by immunocytes of any Ig ass with the possible exception of IgE. This accords with weral studies indicating that B cells of a specific clone are gertically multipotent with regard to their H chain product<sup>20</sup>. Mny circulating B cells have both IgM and IgD in their surface mmbranes 21,22; and the simultaneous presence of IgM in the nembrane and IgG in the cytoplasm has also been described3. In general, however, the secretory product of a single mattre B cell is of only one Ig class and it has been postulated tha there may be an intraclonal switch from expression of IgM synthesis to IgG, and perhaps to IgA24. The finding of IgD-conaining plasma

cells adjac lymphoid follicles indicates that IgD may be expressed in such a development. The presence of J chain in most of cells moreover suggests that this polypeptide represents basic gene product of B cells, the synthesis of which is ried only after prolonged clonal proliferation. In lympholicles and adjacent to glandular epithelia, continuous cl expansions from immunocytes that have recently swl their H chain product may occur as a result of frequent ptation of new antigenic material. This is in

Immohistochemical demonstration of J chain in human tissi. Paired staining was performed with a 'green' anti-J-chain njugate combined with a 'red' conjugate specific for IgA, Iglor IgM. Right column: records of selective red emission. Lecolumn: a-d, records of selective green emission; e, f, double posures. a, Field from gingival section with two intense J qin-positive cells (arrows) which are not IgA immunocyte b, Comparable field from section adjacent to a showing a w J chain-positive IgG immunocytes (arrows). c, Area beath the surface epithelium of nasal mucosa containing to intense (left arrow) and three faint (right arrow) J cin-positive IgG immunocytes. d, Field from glandular aa of inflamed colon mucosa (Crohn's disease) containing imerous J chain-positive IgM immunocytes. Left arrow, dicates a negative cell, and right arrow, a positive one. e, Fieldrom glandular area of normal colon mucosa with two IgM ces which are stained brightly for J chain (mixed colour in lefpicture), and numerous more or less faint, green cells which a neighbouring section were shown to be IgA immunocytes, Part of an area adjacent to a tonsillar lymphoid follicle. The were a few J chain-positive IgM cells (two shown), and everal other immunocytes brightly fluorescing for J chain. Staing of neighbouring sections demonstrated that most of tese contained IgD, and some contained IgG.

accordance wih the fact that the largest number of J chainpositive IgG cells were found in these areas.

Studies of nouse and human cell lines have provided contradictory information with regard to the intracellular events in the Ig polymerization process<sup>5,25,26</sup>. The SC-affinity test directly

demonstrates that normal gland-associated human IgA and IgM immunocytes must contain cytoplasmic subunits in an arrangement with J chain comparable to that constituting the SC-binding site of the extracellular immunoglobulins<sup>16</sup>. For IgM3, as well as IgA, this arrangement may be a dimer which is not necessarily covalently stabilised initially. If this dimeric configuration is likewise expressed in the membrane of IgM and IgA cell precursors, these B lymphocytes may by contact with SC-producing epithelial cells or interstitial free SC, receive a stimulus on their mucosal recirculation route, which induces their settlement and local proliferation. In addition the J chain-dependent SC-binding site of extracellular immunoglobulins may mediate the epithelial reception and the selective glandular transmission of dimeric IgA and 19S IgM<sup>15,27</sup>. This peptide therefore seems to be important in the evolution of the mucosal immune system.

This study was supported by the Norwegian Research Council for Science and the Humanities, the Norwegian Society for Fighting Cancer, and Anders Jahres Fond. I thank Dr J. Mestecky of the University of Alabama for the reference serum to J chain, and Mrs Karen Mette Halvorsen and Mrs Solfrid Stavik Vold for technical assistance.

#### Anti-tumour cytotoxic effects mediated by minor and major cell populations of lymph nodes

SEVERAL studies have demonstrated that cell-mediated immunity to animal and human tumours can be measured in vitro by colony inhibition or microcytotoxicity tests in which immune lymphoid cells kill and/or inhibit the growth of tumour cells<sup>1,2</sup>, and more recent studies have attempted to extend these results by measuring the relative contributions of T and B lymphocytes to the anti-tumour effects noted<sup>3,4</sup>. The principle upon which these latter experiments have been based is that selective depletion of one or the other lymphocyte subpopulation, followed by measurement of the capacity of the residual population to produce an effect, should indicate which subpopulation is operative in the system. But, conclusions drawn from such experiments are critically dependent upon the assumption that the remaining lymphocyte subpopulation is not contaminated with other cell types; or, if it is, the contaminating cells are unlikely to be effector cells in the assay used because they are inactive and/or infrequent. Acceptance of this assumption requires careful evaluation; for as we have observed in the present investigation of effector cells operating during the primary immune response to murine Moloney sarcomas, a cell type of low frequency may contribute in a major way to the cytotoxic effects noted in vitro. Furthermore, these cells are present in considerable numbers within regréssing tumours in vivo.

MSC or MCA-12 tumour cells (800) were cultured for 42 h with 8×10<sup>s</sup> effector cells in Linbro Multidish Disposo trays (0.2 ml per well); trays were washed by immersion, surviving tumour cells were pulsed for 6 h with IUdR (0.2 µCi per well), and trays were washed again. For effects of varying tumour cell and effector cell number in the assay see ref. 6.

LNC were used as such or were passed through divinylbenzene/polystyrene bead columns (37° C) to remove adherent LNC. Non-adherent LNC preparations contain <0.2% phagocytic macrophages and >99% lymphocytes of which 20-25% are Ig and 65are θ-bearing cells.

5% are 6-bearing cens. CPM IUdR (mean±s.d.) remaining adherent at the conclusion of

the cytotoxicity test.

Percentages evaluated by Student's t test: ns=not significant; †P < 0.001.

Moloney sarcomas were induced in 4-week-old female BALB/c mice; and 12 to 18 d later, when tumours were regressing, lymph node cell (LNC) suspensions were prepared and their effects on syngeneic tumour cells were determined as previously described<sup>5-7</sup>. Cell-mediated killing of tumour cells (cytotoxicity test) was measured by labelling o lines of tumour cells with 125I-iododeoxyuridine (IU, DNA isotope, and culturing them with effector cells fh. Cellmediated inhibition of tumour cell growth (cyis test) was assessed similarly except that unlabelled ur cells were cultured with effector cells for 42 h and turviving tumour cells were pulsed with IUdR for 6 h. In assays, the number of surviving adherent tumour cells ctes with the amount of radioactivity remaining adherent; culture surface<sup>8</sup>. We have recently made an extensive as of the variables influencing the results obtained in this system, and the work reported here is based on these find

Whole LNC obtained at the time of tumour reon killed both Moloney sarcoma cells (MSC) and unre tumour cells such as polyoma virus-transformed 3 broblasts (PY)7 and methylcholanthrene-induced sarcomal (MCA-12)6. A representative cytostasis test in which MSMCA-12 were cultured with LNC demonstrates that both kif tumour cells were killed by LNC from mice whose urs were regressing (Table 1). PY and MCA-12 tumour are unrelated antigenically to MSC by the followinteria: (1) serum from mice with regressing Moloney sarce binds to MSC but not to PY and MCA-12 as detected 25I-rabbit anti-mouse immunoglobulin (Seeger, unpublis and (2) neither PY nor MCA-12 has C-type particles orip-specific

Experiment (1): cytostasis test as in Table 1 exc that  $4 \times 10^5$ LNC were cultured without or with silica (40 µg | 1 Min-U-Sil 5 µm diameter (Whitaker-Clark-Daniels)) for 24 h be unlabelled MSC were added. Cultures were then continued 42 h when surviving MSC were avaled with 1112

surviving MSC were pulsed with IUdR.

Experiment (2): cytostasis test performed as in Τε 1. NALNC (5×10°) were treated with anti-θ C3H serum (raisen AKR mice by repeated injections of C3H thymocytes and used a dilution of 1/10 which was on a plateau of killing against BAL/LNC; specificity of antiserum for the  $\theta$  alloantigen demonstrd by showing that absorption with BALB/c brain removed all cyoxic activity) or normal AKR serum (30 min, room temperatur Both groups then were treated with guinea pig complement (1 dilution, 30 min, 37° C). Dead cells were removed by incubon in 0.25% trypsin in Tris buffer (5 min, 37° C) followed by filtron through a chart filter (belief of the magnitude). short filter (boiled cotton wool).

Experiment (3): cytotoxicity test: 2,000 IUdR-labed MSC were cultured with 8×10<sup>5</sup> effector cells for 48 h. Effectcells prepared as in Experiment 2.

Percentages evaluated by Student's t test; ns t significant; < 0.01; ‡P < 0.001.

\*MSC was the target cell in these experiments.

antigen which MSC does have. Therefore, the bserved cytotoxicity is likely to be truly nonspecific and nodue to crossreacting antigens.

By contrast, non-adherent LNC (NALNC) btained from mice whose tumours were regressing killed ISC but not antigenically unrelated MCA-12 (Table 1). lote that the magnitude of killing mediated by NALNC in the and previous experiments6 is less than that mediated by an eual number of whole LNC. Specific killing by NALNC agree with our previously reported observations6,7 and with serol-gically defined specificities.

We sus that the dominant effector cells in whole LNC suspensiore macrophages, even though they account for only 2.5% effector cells, because: (1) activated macrophages kispecifically8,8; (2) nonspecific killing mediated by LNC isbrogated when T lymphocytes are removed by treatment anti-θ C3H serum and complement<sup>7</sup>; (3) macrophae adherent cells, and removal of adherent cells abrogates ecific killing<sup>6,7</sup>; and (4) macrophages are present in greaterbers in immune than in normal control LNC suspension compared with 0.9%) (proportions of macrophagre estimated from cytocentrifuge preparations following ation with polystyrene particles as markers of phagocytoso further test the possibility that macrophages, although ident in number, were the dominant effector cells, wholic were cultured with silica for 24 h to kill macrophag; and then unlabelled tumour cells were added to thaining LNC (Table 2, experiment 1). Because low number NALNC  $(2 \times 10^{5} - 4 \times 10^{5})$  are not detectably cytotoxic is assay system6, we expected that removal of macrophagrom 4×105 LNC by treatment with silica would abre the cytotoxic effect. Indeed, immune LNC treated in a manner did not significantly inhibit the growth of C, whereas untreated immune LNC did so. Control expents indicated that silica was not affecting lymphocyte/ival.

The specialling observed with NALNC is most likely due to lymphocy for such preparations contain > 99 % lymphocytes and Ichan 0.2% macrophages. To determine if this killing was endent on T lymphocytes, NALNC were treated with anti- $\theta$  ( serum and complement (Table 2). In two such experiments e a cytostasis test (experiment 2) and the other a cytotoxicitest (experiment 3), treatment with normal AKR serunnd complement (control treatment) did not affect the diffices between normal and immune NALNC, but treatment wanti-0 C3H serum and complement markedly decreased obmpletely abrogated the differences between them. We inpret this as indicating the dependence of the specific effec NALNC on T lymphocytes. As yet we have no evidence on ether the cytotoxicity mediated by NALNC is due to dit T cell killing or is mediated by other cells whose action pends on T lymphocytes.

A number other recent studies of the immune response to primary Moley sarcomas have been aimed at determining which cell tys mediate cytotoxic reactions in vitro. Lamon

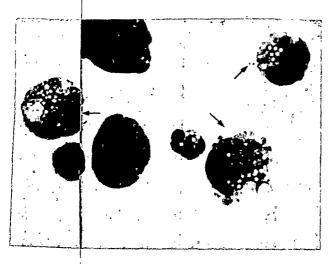

Fig. 1 Cytcentrifuge preparation made from a Moloney sarcoma. The limour was trypsinised to provide a cell suspension which was the incubated with polystyrene beads. The beads then provide markers of phagocytic cells such as macrophages and polymorphoniclear leukocytes. Three macrophages are arrowed; the remainingcells comprise two large cells which are tumour cells and one lymphocyte and one polymorph (containing beads).

Macrophages make up 35% of the cells present.

et al.3, using a microplate system involving visual counting of surviving adherent tumour cells, have reported that immunologically specific inhibition of tumour cell growth was mediated by mixtures of whole LNC and spleen cells during the development and after the regression of Moloney sarcomas. Cell separation experiments suggested that both T and B lymphocytes were responsible for the effects noted. Plata et al.4 have reported similar results in a microplate assay, but in a 51Cr release assay the same group of workers11 and others12 have found that T lymphocytes are the only active population at the time of tumour regression. The reasons why these studies have not detected macrophage mediated effects when using whole LNC or spleen cells is unclear, for when Moloney sarcomas are regressing, LNC and spleen cell suspensions contain 2.5 and 10.1% macrophage respectively?. Even if preparative methods are used to remove adherent and phagocytic macrophages from spleen suspensions, we have found that non-adherent and non-phagocytic precursors soon become mature macrophages capable of cytotoxicity. Possibly the tumour cells used in previous studies3,4 were not susceptible to macrophage-mediated cytotoxic effects. Certainly, the relatively short term 51Cr release assay may be less able to detect macrophage effects than the 48 h test which we use.

Our experiments demonstrate that macrophages, a minor non-T cell subpopulation of lymph nodes, can be potent cytotoxic cells in vitro overshadowing the effects of lymphocytes. This observation suggest caution in interpreting experiments in which effects of different cell types are being assessed if such preparations are contaminated by even small numbers of other cell types. In the host response to primary Moloney sarcomas, cytotoxicity mediated by macrophages is nonspecific, whereas that mediated by lymphocytes is specific and is dependent on T lymphocytes. None the less, the cytotoxic effects of macrophages in vivo may be of considerable importance. Certainly, regressing Moloney tumours contain large numbers of such cells (Fig. 1). We are attempting to clarify the relative importance of macrophages and lymphocytes as effector cells in tumour rejection by studying the cytotoxic potential of cells taken directly from tumours.

#### Intestinal transport protein

We would like to take issue with the recent letter of Faust and Shearin<sup>1</sup> reporting on a "sugar and amino acid transport protein . . . from hamster jejunum".

The questionable significance of the observed p-glucose binding proteins from the intestine to intestinal Na+-dependent monosaccharide transport has been discussed in detail by Eichholz and Howell<sup>2</sup> and Garcia-Castineiras et al.3. In addition, we would like to point out that it is highly misleading to give a binding protein the adjunct transport when it does not fulfil one of the fundamental requirements for transport, namely high rates of binding and debinding. That the debinding of D-glucose is extremely slow has been previously noted by Eichholz et al.4, and can be deduced from the gel chromatography data of Faust and Shearin<sup>1</sup>. In fact, D-14C-glucose remains tightly bound to a macromolecule during passage through Sephadex G-751. If anything, this tight binding suggests that the "protein" plays a role in storage rather than transport of D-glucose.

That the bulk of the observed pglucose binding may be unrelated to transport is also indicated by one of our observations. We have investigated Dglucose transport in isolated and highly purified vesicles of brush border membrane from rat small intestine5,6. Pre-

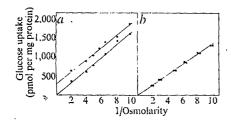

Fig. 1. Effect of medium osmolarity on D-glucose uptake in isolated intestinal brush border membranes. Preparation of membranes (in 100 mM cellobiose, 1 mM HEPES, adjusted to pH 7.5 with Tris, and 0.1 mM MgSO<sub>4</sub>) and the uptake procedure have been previously described<sup>5</sup>. Uptake was measured from a medium with the following final composition: NaSCN (25 mM), Tris-HEPES (1 mM), MgSO, (0.1 mM), D-1-3H-glucose (1 mM) and L-1-14C-glucose (1 mM) and enough cellobiose to give the indicated osmolarity (shown as inverse osmolarity). Time of incubation: p-glucose, 10 min; L-glucose, 20 min; temperature, 25° C. The lines were calculated by regression analysis (correlation coefficient in all 

viously, D-glucose uptake by the isolated membranes had been measured mainly at pH 7.5. When investigating D-glucose uptake as a function of pH we noticed that with lower pH values the equilibrium uptake increased above the pH 7.5 level. This 'extra' D-glucose uptake exhibited a pronounced maximum around pH 6.0. The time curve of uptake did not seem to be altered by pH, that is, constant levels of D-glucose were always reached by 5 min incubation at 25° C. The absolute amounts of 'extra' uptake varied between 0.3 and 1.0 nmol per mg membrane protein (measured at 1 mM D-glucose) in different preparations. Bacterial contamination is not responsible for our observation.

To determine whether the 'extra' Dglucose uptake represented binding to' the brush border membrane or transport. into the intravesicular membrane space we measured the dependence of D- and L-glucose uptake on the osmolarity of the suspension medium at pH 7.5 and pH 6.0 (Fig. 1). D- and L-glucose uptake at pH 7.5 and also L-glucose uptake atpH 6.0 can be accounted for totally by transport into an osmotically active space (line goes through the origin). The 'extra' D-glucose uptake at pH 6.0, however, is independent of the medium osmolarity suggesting binding (300 pmol per mg protein in Fig. 1; intersection of the line with the ordinate).

The rate of p-glucose transport was found to be equally fast at all pH values between pH 8.0 and 5.0. That transport can proceed without measurable binding, at least on the scale indicated in Fig. 1, suggests to us that transport and measured binding are unrelated. At the moment, we have no hint as to function or origin of the p-glucose binding.

DR FAUST REPLIES-Since brush border region of the intesmucosal cell is a digestive-absorptiganelle, the pumping of monosacles and amino acids across this enrganelle must be considered in the mism by which these substrates are mulated against their concentrationadients within the cytoplasm.

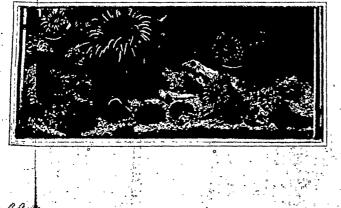

The phenomenon that fer and Sigrist-Nelson have obserconcerns the movement of p-glucoross one section of the structurally dex brush border, the plasma membrie agree that their observed p-glucoinding is not related to transport an feel that it could be caused by bindirdisaccharidases in the plasma mane. Our binding protein, however, ocated in the core fraction of dised brush borders which does not cin hydrolytic enzymes. It possessees for the Na+-dependent trapping specific monosaccharides and amacids that are derived either indire from the hydrolysis of dietary oligostarides and polypeptides or directly m dietary monomers in the intestinumen. We have shown that the specty for this binding is similar to that the active transport of these substancy the small intestine. Furthermore, the servations could not be attributed to terial contamination.

We visualise that our isled binding protein is involved in the 1-dependent active transport of sugaand amino acids from the core region the brush border into the cytoplasnThis occurs after the initial penetration hese monomers through the plasma embrane.

We concede, however, this protein can only be regarded proionally as a transport protein until binding is adequately studied. Debling of the sugar and amino acid terry complexes could be triggered by a offormational change in the binding pron caused by the low intracellular Na+ incentration, the replacement of Na+ the ternary complex by K+ from the gh K+ intracellular region, and by a imbination of these phenomena with theid of energy derived directly from cellul metabolism. None of these conditions vas prevalent in our Sephadex G-75 fractionation therefore D-14 glucose and studies. L-14C-histidine remained tihtly bound to the isolated protein subuits.

**John Gribbin &** Stephen Plagemann

Earthquakes are the most devastating natural phenomenon known to man and have taken an enormous toll of life and property throughout human history. Until now, we have had no accurate means of predicting their occurrence although much effort has been put into research to discover the possible mechanisms which trigger off these cataclysmic events. John Gribbin and Stephen Plagemann present in this book a new model which aims at predicting earthquakes through the study of the hitherto unrecognized and apparently unrelated phenomena of planetary alignments, sun spot activity and the solar wind, and their vital role in determining the course of natural events on earth. These causal links are shown to affect earth movements in active seismic areas and thus unleash the powerful forces which areas and thus unleash the powerful forces which cause earthquakes.

But their research goes beyond the general model. A particularly unusual planetary alignment will occur within the next articularly unusual planetary alignment will occur within the nexten years and the authors argue a convincing scientific case for major earthquake activity during that period and stipulate the year in question. In particular they show that an earthquake of devastating proportions may well occur along the highly active seismic zone of the San Andreas Fault in California which runs through the cities of Los Angeles and San Francisco. The physical, social and economic implications of a major earthquake in this populous area are far-reaching. They make this a book which should be read by all scientists and non-scientists concerned about the effects of natural and non-scientists concerned about the effects of natural events beyond the immediate control of man.

HUMAN AND ECOLOGIC EFFECTS OF NUCLEAR POWER PLANTS edited by Leonard A. Sagan, Palo Alto Medical Clinic, Palo Alto, California. Introduction by Rolf Eliassen. (15 Contributors) There is a widespread need and public desire to better understand nuclear power and its consequences. Reactor technology and its ecologic effects often exceed the detailed understanding of many experts. Although the book is directed toward an exposition of human and ecologic effects, the first section details reactor design and engineering. Such material is necessarily included since many readers will be unfamiliar with reactor design and should have available some understanding of reactors, their operation and methods of generating and releasing radioactivity. Public attention has been focused on nuclear power because of the concern for the environment which has suffered from past and present technology. Contamination of air and water with reactor-produced radioactivity has aroused fears of radiation hazards to both persons and the environment. The mood of the public has generated the desire for wider participation in decision making and the loss of faith in those institutions to which these decisions have traditionally been delegated. '74, 560 : pp. (7 x 10), 138 il., 86 tables, \$34.50

FISH CHROMOSOME METHODOLOGY, by Thomas E. Denton, Samford: Univ., Birmingham, Alabama. This practical guide to the identification of fish chromosomes and techniques for their study is written for beginning and veteran investigators interested in the cytogenetics of fishes. Beginning with an introduction to the classification and maintenance of fishes, the author shows how to obtain and present chromosome data, provides a checklist of chromosomes containing the numbers and karyotypes from over 500 fishes, and presents a current analysis of the fish karyotype. The techniques presented include primary tissue cultures, leucocyte cultures, and working with epithelium from fins, scales, gills and internal organs. Advantages and disadvantages of each technique are given. '73 176 pp., 10 il., 1 table, \$11.50

LECTURES OF THE PHENOMENA OF LIFE COMMON TO ANIMALS AND PLANTS, Volume I by Claude Bernard. Translated by Hebbel E. Hoff, Roger Guillemin and Lucienne Guillemin, all of Baylor College of Medicine, Houston. Bernard's work shows the necessity of knowing objectively the invariable elementary properties which are the fundamental basis of all the manifestations • of life. This is the goal that the general physiology proposes for itself. Life lies truly within the organic elements; it is here that the real physiological problems should be placed. In this volume Claude Bernard has summarized the whole of his doctrines, and it is the most complete and the most systematic work that he leaves to the scientific world. This book is in reality a program for general physiology compiled in 1878 from nine lectures delivered at the Museum d'Histoire Naturelle, Paris, France. An excellent historical account of the work of one of the 19th century's most prominent physiologists. '74, 336 pp., 80 il., \$12.95

# reviews

THE focusearch into the process of technol innovations seems to have shifteently to the developing countries. the problems of 'high' technologyscience-based industries. one now hincreasingly about transferring teogy to the countries of the Third Y; and it is not advanced technology intermediate, or other appropriatchnology. This development in tanguage of technology transfer re; the simple fact that innovation i complex social (some would say cal) process and that the experience he western nations with technologiclevelopments will not transplant & to other countries trying to make transition to industrialisation.

The expace of western nations over the lavo hundred years forms the historicackdrop to the manifold proble of making and implementing deons intended to bring about modernisation, the aur makes clear, involves the marriagf technology and civic life. By this means that every developing sow must be viewed as a complex of already existing and functioning tial and economic processes and tho decision to introduce new technoly can hope to succeed without an erational understanding of this fact. if to guide the reader in the implicans of these facts, the author painkingly documents the industrial hirry of the western world

## **Industrial** revolutions

M. Gibbons

Technology and Civic Life: Making and Implementing Development Decisions. By J. D. Mongomery. Pp. 239. (MIT: London and Cambridge, 1974.) \$12.50.

and points out the relevance of certain developments in the contemporary context of developing countries.

A recurring theme in the book is the changing relationships among three modes of development politics; national planning, local options and individual choice—as forces that can direct the use of technology for advancing the quality of life in the undeveloped countries. This theme also provides the introduction to the theoretical structure of the work-a structure, it seems, that is deeply rooted in a behaviouralistic theory of politics. It is important to remember, cautions the author, that technological change implies changes in behaviour and that these cannot be brought about edict or fiat but must begin with a thorough grasp of the attitudinal status quo and build from that basis. But the modernisation of behaviour also cannot ignore the politics and structure of the community at the local level because individuals form an integral part of this structure and constitute its 'politics'. By the same

token, modernisation cannot be achieved in any significant way by the transformation of the community at the local level alone. Because technological development requires the reorientation of all communities more or less simultaneously, unless it is directed at the national level modernisation will be a fragmented affair. Thus, the characterisation of the developmental problems is, in terms of these levels, intimately linked together. Accordingly, there are also three 'analytical orders' or levels of decision to be considered in applying technology to social purposes. The first order decisions are those which define and develop programmes for the purpose of benefiting identified elements of the society. The second are those that identify the administrative organisation or combinations of institutions that are to be assigned the role of moderniser and change agent. The third prescribes the incentive system by which administrators are to elicit modernising responses from citizens, participating in the programme.

Because of its tight organisation and conceptual sophistication the book makes interesting and stimulating reading. Further, because even in advanced societies there are sectors which are becoming modernised or in need of becoming modernised, there is much in the way of insight and common sense for those in charge of regional development policies.

SPEAKING alne with a personal interest in the engiring applications of holography, I find reading this book to be a refreshinexperience. In addition to contributing ersonally, the editor has gathered cdributions from 14 other internationaly recognised experts in fields of optal measurement or display. Although hography features prominently the bok is by no means confined to that topi nor is it just about nondestructive sting. The title is a bit artificial ancseems almost to have been chosen as a excuse to bring this work together. In pite of that, the aspects of nondestructie testing do form a thread of continuitythrough a work on optical measuring tehniques which are biased heavily to thise which use lasers and to a lesser extert to those using coherent radiation in the form of microwaves or ultrasonic

## **Optical measuring** techniques

John N. Butters

Holographic Nondestructive Testing. Edited by R. K. Erf. Pp. xvii+442. (Academic Press: New York and London, July 1974.) \$28.00; £14.00.

coherent radiation for measurement or testing would do well to read this book. It contains descriptions of practical test layouts and a wealth of experimental 'tips' which help to maximise the usefulness of experiments from a data retrieval point of view. Typical examples are given but some readers will be disappointed to find that these are based in the main on laboratory experiments. Contributions are sectionalised by the author and fall into two categories: substantive material which Any would be user of techniques of forms the core of the book; and reports University, to mention but two.

on significant developments. Sections in the first category contain mathematical backgrounds to the topics covered but there are some abrupt changes in style and technique. Presentation ranges from the quotation of relevant formula to fairly complex derivations extending to. two or three pages. Readers wishing to gain benefit from the theoretical aspects would need a grounding in advanced mathematics.

All in all this is an excellent book for the serious user; it is well referenced and obviously emerges from a group well informed and well practised in their technology. Cited work is mainly of American origin so it may be appropriate to note that the techniques described are available in the UK at centres such as the National Physical Laboratory and the Mechanical Engineering laser facility at Loughborough

## Nuclear techniques

Techniques in Nuclear Physics. By J. B. A. England. Part 1, Pp. viii + 1 - 312; Part 2, Pp. viii + 313 -697. (Macmillan: London and Basingstoke); (Halsted Press, distributors, USA, July 1974.) £10.00 boards; £4.50 paper.

In recent years a wide variety of experimental techniques has been developed which allow measurements of increasing sophistication on the products of nuclear reactions. The techniques are well known to a few specialists but descriptions of them are often only available in scattered articles in specialised journals. The two volumes by Dr England thus fill a real need by providing a comprehensive summary of the more important techniques in a readily accessible form.

The first chapter is devoted to detectors and covers the photographic method, solid dielectric track detectors, gas ionisation chambers. scintillation and semiconductor detectors, spark chambers and Cerenkov and neutron detectors. There follows an account of instrumentation in general, including particle beam detection. measurement and handling, scattering chambers, electronics and on-line computers. The final chapter of Part 1 summarises various types of accelerators: the Cockcroft-Walton voltage doubler, the dynamitron, the Van der Graaf generator, insulating core transformers, linear accelerators, cyclotrons and cyclograffs.

The second volume covers magnetic spectrometers and spectrographs, and particle identification techniques. Among the latter are time-of-flight techniques, techniques of single detector identification by telescope, and problems associated with passing detectors. Then comes a summary of coincidence measurements, angular correlations and lifetime measurements with accounts of the general theory of angular correlations, gamma-gamma and particle-gamma techniques, and correlations with oriented nuclei and huclear lifetimes. The final chapter is devoted to polarised beams and polarised targets.

So numerous are the techniques today that even in a pair of volumes of some 700 pages it has been necessary to restrict the coverage by omitting the Mössbauer techniques, the techniques of beam-foil spectroscopy and the study of the capture  $\gamma$  rays produced by the interaction of polarised thermal neutrons. In other cases where good review articles are available, as in the subject of angular correlations, the discussion has been curtailed accordingly.

The level of the discussion is suitable for senior undergraduates and for first and second year graduate students, and gives a clear account of the basic. physics underlying each technique, together with many references to papers and monographs in which more detailed accounts can be found. There is a comprehensive list of references at the end of each chapter but, unfortunately, no alphabetical list of authors. The subject index is inadequate, so that it could take some time to find the account of a particular subject.

## **Energy spectrum**

Energy: Demand, Conservation and Institutional Problems. Edited by Michael S. Macrakis. Pp. xxvii+556. (MIT Press: Cambridge and London, 1974.) \$25.00.

To undertake the comprehensive reporting of 38 conference articles requires dedication, particularly when the modelling of energy systems is the subject of a major part of the work. The fact that Michael S. Macrakis achieved this objective in a hard backed volume of 530 pages within about a year is noteworthy.

The editor can be excused for rele-

gating another 28 article stract form, to an appendix foons of space, delayed submissionecause they were "addressed to stergy". To add variety and intere best of the articles on sunshind have been included in full and mewhat heavy going sections on ate and disaggregate modelling cove been reduced without great los

The sections of the behich include supply and demannsportation, and conservation, p: helpful subdivisions for experts wish to confine their reading. Ehe energetics enthusiast would however, be impelled to read thok from cover to cover as it m periodic random selection of a fessages for

short perusal.

The reader interested ir prospects and problems facing a wtrying to supply future energy need find half a dozen relevant pap Another dozen contain useful data can thus reduce searches elsewh A great deal of the data and submatter is, however, of relevance ly to the United States.

Readers of this volumill quickly appreciate that national tern in the United States is having aitive effect.

Improved methods fonergy production and applicationnning have been developed. There, a greater awareness of the fac affecting energy economics and thterrelation of the subject with envimental and real resource costs. The is also an appreciation of the neeor a wider variety and depth in rgy assessments, and there has be more concentrated research to irove energy technology.

It was good to note the few European authors were able contribute to the conference. A teafrom Queen Mary College, Londo were very active in providing so interesting papers on world energyodelling, the implications of nation policies on world energy, oil transpation studies, energy economics and atmospheric pollution. Several of the deal with components of the mathatical model being built up by the Ergy Research Unit at Queen Mary ollege, which should become an inchsingly useful tool for policy assistane in Britain.

But there are many petical technological problems to I solved and policy decisions to be nde before the editor's introductory cestion is answered for each coutry operating within its own uniqe limitations. "How quickly", he ass, "with what set of energy sources and at what prices can a supply of energy be secured, which satisfies environmental and safety constraints thile accommodating prescribed econonic paths?"

There tant encouragement here for thoseho incline to the view that gene methods will solve our pest probs and that the end of insecticide nigh.

Althoughere is little discussion of future pectations for these approaches pest and vector control, the book as a succinct coverage of the subject date with, perhaps, a bias towal medically important insects, in rticular, mosquitoes; no doubt a lection of the author's experienced interests. I. Maudlin

Biological ntrol by Natural Enemies. By Paul Dach Pp. 323. (Cambridge University Press: London, £5.50; \$14.

This is a mely and valuable book, written in haracteristic style by one of the works leading biological control worker It highlights the disasters that have flowed the heavy use of broad-spect|m pesticides and emphasises the highly advantageous costbenefit ratioresulting from successful biological ontrol projects. Numerous historical alunts of successful or partially successful campaigns are given, which highlight the colossal difficulties the early wrkers laboured under in and intuition as well as sound scientific understanding, in searching out the native range of natural enemies.

DeBach rihtly emphasises the crucial importance of correct taxonomy and of seeking gographical races that are

G. Dav Pp. ix+158. (Academic ploration for natural enemies has not Press: h and New York, August yet been attempted for more than 5% of the world's pests and it is certain This brovides a useful overall that an even lower percentage of weeds should study. statemel current and proposed has been considered for attack by this methodshe autogenous control of means. The potential of classical bioagricultud public health pests. It logical control therefore continues to

DeBach makes a point that will bear emphasis: "How to put everything together to choose a potentially effective enemy beforehand with certainty is still beyond our grasp"; and further "... the natural enemy ... considered The tecles for rearing, for ex- to be best often turned out to be inconsequential and, in fact, the best one even may be overlooked for years, as was Cyrtorhinus, the egg predator of the sugar-cane leafhopper." Although attempts to assess in advance the potential of biological control agents must

## More campaigns in the pest war

continue (and they are gradually providing a basis for sounder choices), there is still no promise of a method for accurately forecasting the impact of a particular species. One could therefore join issue with Professor DeBach when he quotes liberally from Alvah Peterson in support of a plea for the study of the 99% of insects that are unimportant to mankind. There is not a shadow of doubt that biological control would languish indefinitely if significant proportions of its rather limited manpower and resources were diverted for this purpose. In this context it is fortunate that there is little evidence that the presence of relatively ineffective introduced enemies hampers the activities of effective agents.

In addition to the great economic potential remaining in 'classical' biological control there are also prospects for the artificial augmentation of populations of natural enemies in relation to certain problems, as when parasites and predators are bred commercially in large numbers for pest control in orchards, poultry houses, dairies and feedlots.

The author also deals briefly with the absence of global air transport, and other non-chemical forms of pest conthe importance of intelligent sleuthing trol, such as the use of resistant plants, cultural and genetic methods, and pheromones, and he gives some useful discussion on integrated control and on the intelligent and selective use of pesticides where that is unavoidable.

This book is obviously not intended adapted to ill the significant climatic as a comprehensive treatise on biologiand ecological situations occupied by cal control-indeed the vast majority

> The Biochemical Mode of Action of Pesticides. By J. R. Corbett. Pp. ix+330. (Academic: London and New York, 1974.) £7.20; \$18.50.

> Any author attempting to describe what is known about the mode of action of poisons faces an unenviable yet stimulating task, for information on the molecular basis of normal physiological activities is frequently incomplete. Impulses pass along nerves by the opening of ionic 'gates' but little is known of the mechanism operating those gates. The same applies to the coupling of electron transport with phosphorylation in mitochondria and chloroplasts, to the biochemical basis of auxin action, and to the mechanism of oxygen release in the second light reaction of photosynthesis.

> As a majority of pesticides probably affect such processes, any account of their action must, of necessity, be incomplete. Dr Corbett is to be congratulated on one of the best attempts so far made to collate available evidence and to present it in a way comprehensible to all biologists possessing a background knowledge of biochemistry and supporting chemistry. It is a valuable reference book for the undergraduate library collection but is not likely to be recommended for private purchase by students of agriculture or horticulture.

> The book comprises three main sections covering compounds acting respectively, on photosynthesis, nerve action and growth. They include tables of pesticides, which are valuable sources of information. The tables would have been even more useful, however, if some indication could have been given of the relative practical importance of the hundreds of compounds they con-

> An author tends to provide space according to the information available on a group of compounds, rather than in proportion to economical importance. Dr Corbett cannot, therefore, be criticised seriously for the fact that some 30 pages are devoted to the useful but locally important urea and triazine weedkillers whereas the crucially important phenoxyalkanoic acids are dismissed in five text pages. Similarly, although it is grand to encounter an afithor with the courage to face the unpopular truth that DDT (despite its manifold faults) has probably saved more lives than any other chemical made by man, it is a pity that it is dismissed in about eight pages.

K. A. Hassall

#### Bird communities

Competition and the Structure of Bird Communities. By M. L. Cody. Pp. viii+318. (Monographs in Population Biology, No. 7.) (Princeton University: New Jersey, July 1974.) \$6.60 cloth; \$3.65 paper.

Copy's book is of more general interest than the title would indicate for he has attempted, with some success, to effect a synthesis between the data of field biologists and the niche and competition models of theoretical ecologists. It will be of interest even to ecologists who hate birds. Cody emphasises the importance of "natural experiments" in understanding community structure, and he makes informed comparisons of mainland and island bird communities, and of California chaparral and Chile matorral bird communities.

He presents a great deal of data that are consistent with the predictions of the theory of community structure developed by the late Robert MacArthur. For example, Cody finds that variation in foliage height diversity accounts for 81% of the variation in bird species diversity in eight North American bird communities (page 128). Cody's extensive field data point out some of the weaknesses of current theory: suppose that one can measure accurately the amount of competition for food, and that one can measure accurately the amount of competition for habitat. How can they be combined into one number that reflects the total amount of competition between two species? If competition along different niche axes (food, habitat, and so on) is independent, then the total amount of competition is the product of the competition coefficients along the different axes. This assumption of independence has usually been made by theoretical ecologists, but Cody found that addition, rather than multiplication of the competition coefficients along the different axes made for better predictions of community structure.

· At times I found the book frustrating because Cody did not develop some of his insights more thoroughly. For example, Cody repeats and partially justifies one sacred cow of ecology-'jack-of-all trades and master of none' (page 55), but on page 68 he shows that species that occupy a broad habitat range often eat a broad range of foods, and argues that this is optimal. Such a species would seem to be a 'jack-of-all trades and master of some'. Another example is his demonstration of character convergence, which he argues is a consequence of interspecific competition. Yet he does not discuss or test the model of MacArthur and Levins that predicts character convergence when a species invades a community in which resource overlap between species is high. Instead, Cody discusses the relationship with interspecific territoriality, but this seems to confuse cause and effect.

Readers not convinced that competition is a major factor in community organisation may not be persuaded by Cody's book. In some cases, alternative explanations are available for the phenomena Cody attributes to competition: for example, geographical separation of closely related species. Nevertheless, Cody presents a large diverse body of data consistent with competition theory. Any refutation of the importance of competition in determining community structure must; account for the extensive observations David C. Culver Cody has made.

## Carbon and light

Organic Photochemistry. By J. M. Coxon and B. Halton. (Cambridge Chemistry Texts). Pp. vii+196. (Cambridge University: London, 1974.) £4.20; \$13.00.

ALTHOUGH several new books on organic photochemistry, aimed mainly at senior undergraduate and graduate students, have been published in the last two or three years the subject is undergoing such rapid expansion that new titles are always welcome. The book under review is divided into five chapters dealing with an introduction to photochemistry; intramolecular reactions of olefinic bonds; intramolecular reactions of carbonyl compounds; cycloaddition reactions; and substitution, oxidation, and reduction. The text is commendably free from typographical errors.

One of the many problems confronting authors in the area of organic photochemistry is the quantity of scientific literature to be covered. There is no possibility of encyclopaedic coverage in a small volume but the information cited should at least be correct. Unfortunately, this is not always so in this book. On page 140 it is stated that 2-methoxynaphthalene affords a (2+2) dimer involving the 9,10 bonds, though, in fact, the dimer formed is of the (4+4) type involving addition across the 1,4 sites of the substituted ring. This structure has been verified by X-ray analysis (Chem. Commun., 978; 1969).

On the whole the authors have kept this book up to date although, inevitably, since the publication date new results have out-dated some of the reaction mechanisms. The book is very readable and gives coverage suitable for the students at whom it is aimed.

William Horspool

## Ising model

The Two-Dimensional Isinel. By Barry M. McCoy and Tal Wu. Pp. xvi+418. (Harvard rsity: Cambridge, Massachusetts; d University: London, Febru 1974.) £12.50.

THE two-dimensional Isingl gives a simplified description of; range of physical systems inch fluids, magnets and binary allwithout question it is the most thory investigated model in statisticahanics. Its main interest is that, to simply formulated, it has a surprrichness and complexity, and through light on the behaviour of systemergoing a phase transition. In 194Onsager performed the major feat lculating the partition function or square Ising lattice in zero fieled found some of its thermodynamoperties. The results profoundly iged the theory of phase transitiond critical behaviour.

Onsager's calculation later investigations by others wnotorious for their difficulty, and made the study of the s model practically a branch cheoretical physics by itself. "In 1962 the Dutch physicist P. Kasteleyn achieved considerable sification by showing that the two-dimonal model in zero field is equivalen the combinatorial problem of png dimers on the bonds of the lati such that each lattice point is cold by the end of one dimer, and inting the number of ways in whichis is possible. This problem has mple solution in terms of the Pfaf of a matrix which can be evaltd without much difficulty. Over thet 12 years the method has become awerful tool by which many more deed properties of the model have b evaluated. The authors of the presemonograph have made notable contritions in this field. Even though the mod is simple in principle, research pars still tend to be hard reading becse of their conciseness and the amot of detail. The aim of this book to give an elaborate exposition of the dimer method and its applicati in various situations. It does not psent a comprehensive survey of all t work which has been done on the ty-dimensional Ising model. The auths have succeeded admirably in the limited aim and have given a carefuexposition of the mathematical techniues involved and the results obtained, or those who want to be acquainted ith the model and its history some eisting reviews would seem preferable. But this book is recommended to anyne aspiring to research in the area ad wishing to acquire a working knowledge of the B U. Felderhof dimer method.

## **Phosphorus** chemistry

T. S. Cameron

The Structural Chemistry of Phosphorus. By D. E. C. Corbridge. Pp. xiii + 542. (Elsevier: Amsterdam, London and New York, 1974) Dfl.250; \$96.20.

sentation they receive. The behaviour of bonds between phosphorus and oxygen atoms is examined in chapter 9 where a discussion on hydrogen bonding is concluded by a summary of P-O bond length (and interbond Chapters 9 (202 pages) cover the angles) over the range of compounds described in the previous five chapters.

Hydrides, nitrides, halides and phosphines are the subject of chapter 10 and the following chapter covers the while still being able to supply single compounds where phosphines act as items of information, in context, with longer discion on orthophosphates. ligands with metal atoms. There, with an evaluation for those with less In these ended structures, as with a vast range of material the author the phospes, the structural dia- has little alternative but to compile high price there will be few research grams are t always easy to inter- a catalogue of the known structures. pret. The coensed phosphates are ex- Details of the ring compounds of phos-

This w a detailed source book amined in chapter 6 where this com- phorus are found in two chapters-12 of the ure of all phosphorus plex series of compounds are ele- and 14—with the first restricted to a simple survey of the structural chemistry of the phosphazines and the second swiftly covering all the remaining ring compounds. Curiously inserted between these two chapters is one on isomerism and optical activity.

The final chapter on cage structures is very short: few containing phosphorus have been reported, and the text is padded somewhat with analogies to cage systems formed by atoms other than phosphorus. There are appendices with a list of unit cell and spacegroup data for phosphorus compounds, an infrared correlation chart and NMR chemical shifts for typical compounds. and 2,649 references.

The book is printed on good quality paper with an elegant typographical balance between text and diagrams. It must have been a proof reading nightmare, but though few errors remain, it is disconcerting to find that a diagram of vitamin B12 (labelled vitamin A) has a structural formula with two very uncanonical carbon atoms.

Throughout the work the author not only exercises a balanced judgement on his source material but presents the evidence on which he bases his judgement. The book will thus be a valuable aid and happy hunting ground for those working in the field of structural chemistry of phosphorus specialised requirements. Despite its laboratories that would want to be without access to this book.

## Crystachemistry

The Major rnary Structural Families. (Crysto Chemistry of Non-Metallic Matals.) By O. Muller and R. Roy. Pp. +487. (Springer-Verlag: Berlin and Iw York, 1974.) DM76; \$31.10.

In his introduion to this first volume in the series of publications on the crystal chemisy of non-metallic materials, Professo Rustum Roy comments on the fact tht few books have been published on the subject of crystal chemistry. If he forthcoming volumes in the series haintain the high standard set by his issue much of the deficit will have been made up.

The introduction is extremely comprehensive and makes certain that the reader understands how to make fullest use of the large amount of information given in the subsequent chapters. Frequently, introductions seem to have been written is an afterthought but here one senses that considerable care has been taken with what should be a most important chapter.

Three major structural families are dealt with in detail: A2BX4, ABX4 and ABX3; with a small number of other structures collected together in table form at the end of the book. Each major structural family is subdivided into individual structural types based on a particular compound. Summaries at the start of each chapter indicate clearly the range of structures covered, thus enabling the reader to locate rapidly any structure of parti-cular interest. Of especial value is the grouping of all the individual structure types into a structural field map at the end of every chapter. The reader can then appreciate to the full the interrelationships of each structure with those of others in the same group. All of the diagrams in the book are of very high quality.

A problem for any author writing on crystal chemistry is how best to present the large amount of crystal data which are required. In this book the authors have chosen to place nearly all such data, in tabular form, into an appendix. Some selected data necessary for an understanding of the text is tabulated in each chapter. The result of this is, however, that almost half of the book is made up of the appendix.

There are two small, but pleasing, aspects of this book: first, the comprehensive and easily found tables of ionic radii, which may well be consulted more frequently than many of the tables; and second, the short sections on the applications of some of the compounds mentioned.

The volume is an excellent reference work and perhaps my only criticism is that the range of structures covered is limited; but one can appreciate that any volume which attempted to cover, in this amount of detail, the whole range of ternary structures would become overlong and unreadable.

M. G. Barker

## Radically speaking

Microwave Spectroscopy of Free Radicals. By Alan Carrington. Pp. ix+264. (Academic: London and New York, June 1974.) £4.80; \$12.50.

This is a highly specialised monograph by one of the major workers in the field discussed. As expected, it is clearly and precisely written and will be invaluable to those interested in, or working in, that field. It is not, however, likely to be of great interest to conventional electron spin resonance (e.s.r.) spectroscopists, nor is it, in any sense, a text on microwave spectroscopy as such.

The 'term 'microwave spectroscopy' is extended to cover all experiments "in which the absorption or emission of microwave radiation by a molecular species can be detected directly or indirectly". The term 'free radical' is extended well beyond the normal doublet state species to include  ${}^{1}\Sigma$ ,  ${}^{1}\Pi$ , <sup>1</sup>Δ, <sup>3</sup>Σ and <sup>3</sup>Π states. Thus, the experimental section includes sections on microwave rotational spectroscopy. gas-phase electron resonance, microwave/optical double resonance, and molecular beam spectroscopy.

Similarly, the 'free radical' species include a wide range of diatomic species such as, CS, A1F, H2, O2, SO, SeO, NF, CN, and the small number of triatomic molecules so far studied, namely NCO, NCS, HNO, CF2, SiF2, HCO, DCO, NO<sub>2</sub> C1O<sub>2</sub>.

The author starts by asking if perhaps this specialised field should be viewed as a "backwater": that it should not be is well demonstrated; in this excellent book.

Reactive Free Radicals. By J. M. Hay. Pp. viii+158. (Academic: London and New York, June 1974.) £4.40; \$11.50.

This book should have a far more explicit title such as 'Structure-reactivity relationships for Organic Radicals'. The author is very much concerned with kinetic parameters derived from reactions in the gas phase. I suspect that the treatment is too biased towards the author's particular conceptions to make it useful for undergraduates, but other workers should find it stimulating.

In the preface we are warned that the book is based on views that are "perhaps even naive" and I fear that this may be a valid warning. Nevertheless, I enjoyed reading it and found several suggestions well worth toying with. I must say, however, that I found an awful lot of glib statements to which I would take exception, such as, "charged radicals are normally produced by electron-transfer at electrodes or from charged species". Or we are told that high-energy radiation pro(if that were always true, I would be out of business). Then we are told that electron spin resonance (e.s.r.) spectroscopy will not detect pairs of radicals formed in solvent cages, despite the fact that one of the most important e.s.r. developments in recent years has been the study of such 'triplet' species.

One very misleading suggestion is that the breaking of the C-C bond in R<sub>3</sub>C-CR<sub>3</sub> molecules may result in the formation of σ-radicals R<sub>3</sub>C--sp<sup>3</sup>hybridisation is implied—despite the fact that the author accepts that R<sub>3</sub>C· radicals are planar or very nearly so. Even more unfortunate is the fact that e.s.r. evidence in favour of this idea is cited, although this has long since been refuted. Again, we are told that a proton hyperfine coupling of  $\pm 16$  gauss for HC $\equiv$ C is "hard to reconcile with a linear structure". Why?

Throughout, very simple valencebond structures are presented (often consuming a lot of space) and the results of sophisticated molecular orbital calculations are completely ignored. I can see very little justification for such an approach in a study which is primarily concerned with structural probdems.

This short book in no sense overlaps with the excellent recent work on radical displacements by Ingold and Roberts, despite the title. The presentation is satisfactory except that references are given at the end of each of the five chapters. As no help is given to the reader, one inevitably turns up the wrong set of references which can prove to be very misleading. Please can we have all references at M. C. R. Symons the end?

## **Nervous systematics**

Evolution of the Nervous System. By Harvey B. Sarnat, and Martin G. Netsky. Pp. xvii+125. (Oxford University: London and New York, September 1974.) £5.75 boards; £4.00 paper.

This is one of the very few comparative anatomy textbooks of reasonable textbook size. It explores neuroanatomy, system by system, in a functional way "through the dimension of time as revealed by analysis of evolution". The book starts with a general overview of vertebrate evolution, and then proceeds with a system by system analysis, including the brain, spinal cord, and the autonomic nervous system. The emphasis is always on how the evolutionary series relates to the structural and functional organisation of the human brain. The book does not cover invertebrate nervous systems, nor those aspects of vertebrate evolution which are divergent from the point of view of the human nervous system. Written by

duces an "embarrassment of products", a neurologist and a neurologist, the text brings out wherossible the bearing of the conve approach on our understandvarious. congenital and pathologiaditions in the human nervous s as encountered in clinical p. The authors do not hesitate al with provocative and speculatints, although always making it where they are being speculativ

There is an extensive bhy, and the references are reast up to date in the majority of sections. The text, however, lacferences to recent developments ie study of central biogenic amirspecially in the accounts of the looeruleus, hypothalamus, and nigroe system. There is an interesting af selected brain sections in differencies.

This comparative panatomy textbook is neatly an indsomely bound, and moderatelyced. The text is highly readable as all the basic anatomical arranges are described, it is complete in and does not require additional ence to a standard neuroanatomy The chapters are well indexed, arithin each chapter the sections are rly headed and subdivided. This me it easy to look up any particulaystem, and enhances the value ole book as G. Raisman a reference work.

## Tropical fores

Tropical Forest and its vironment. (Tropical Ecology Seric By K. A. Longman and  $\overline{J}$ . JeniPp. x+196. (Longman: London, Jui974.) £1.95.

This lucidly written andeful booklet belies its ambitious titler, as stated in its preface its principontribution is a synthesis of results ohysiological experiments on Ghanai forest trees carried out in controlleavironments, and parallel field investions; both are then related to sting knowledge of rain forest ecoly. The careful accounts of the autho experiments provide new and reward insight into West African rain fores but attempts to relate them to fores elsewhere in the tropics, and more rticularly the additional general chapis on subjects unrelated to the experients, are of variable quality, as th authors too often assume, wrong that West African forest condition are universal in the humid tropics, he account of tropical forest soil, for istance, is misleadingly over generased; that on biotic factors is so suerficial that it would have been bette omitted; previous data is somethes misquoted (notably in Fig. 4.9); a'd much recent literature is left unconsisted. But there are well designed diagrams and 25 pages P. S. Ashton of photographs.

# obituary

#### M. Ewing

MAURICE EWING, the eminent oceanographer, died in Galveston, Texas, on May 4, 1974.

Ewing attended the Rice Institute (now Rice University) for both his undergraduate and graduate education in Physics. On receiving a Ph.D. in 1931, he was appointed to the Physics Department at the University of Pittsburgh, then at Lehigh University where William Bowie, Richard Field and Walter Bucher introduced him to the problems of seagoing geophysics. Using equipment and help from F. A. Vening Meinesz, pendulum gravity measurements at sea were begun. With his students (and lifelong associates) Vine. Webster, Woolard and Worzel, techniques were developed for making seismic measurements with the explosive source and automatic recording equipment on the seafloor. In this manner, the first marine seismic refraction measurements were attained just before the outbreak of the Second World War. Sediments were found to be thicker over the continental shelf than in the deep sea.

In 1940 Ewing took leave of absence (he was then an Associate Professor of Geology at Lehigh) to move with his group to the Woods Hole Oceanographic Institution and work problems of submarine detection in association with Columbus Iselin, who had become impressed with the decisive role played by the thermocline in determining sound transmission characteristics in the upper ocean. Ewing and Vine adapted the Sphilhaus bathythermograph for use on vessels while underway. Iselin, Ewing and Worzel produced a manual, Sound Transmission in Sea Water for use in a basic training course at Woods Hole for Naval Officers. Ewing and Pikeris were the first to recognise the importance of the minimum in soun velocity for long-range sound transmission (SOFAR). The expected waveguide effect was demonstrated with a dramatic test: a small explosive was etonated at depth in the eastern Atlantc, and recorded on the western side with hydrophones suspended into the SOFAR channel. Ocean bottom photography, developed as a sideline n previous years, was applied to undewater shipwreck photography. With some incredible luck, Ewing obtained a picture of a wreck's nameplate; he would carry this in his

pocket to convince sceptical Naval officers of the usefulness of underwater photography for identification purposes. The first seabottom wave recorder was built by Ewing.

In 1946 Ewing and some of his group returned to academic work-this time at Columbia University, where they soon founded the Lamont Geological Observatory (now Lamont-Doherty). Ewing served as Associate Professor of Geology, then Professor, occupying the Higgins Chair from 1959 to 1972. Under Ewing's direction, the Lamont Observatory moved into the forefront of geophysics and geology, especially as related to the oceans. Seismic refraction measurements were resumed, this time not with bottom-dropped instruments but with suspended hydrophones. Ewing developed and used towed magnetometers (first flux-gate, later nuclear precession), and initiated continuous reflection profiling with air-gun sources. He improved techniques for precision depth recording, gravity measurements (from submarines and later from surface vessels) and long piston coring, and carried out heat-flow measurements in conjunction with piston coring.

Yet another contribution was the suggestion that turbidity currents played a vital role in sedimentary processes. The study of the sedimentary evidence led to a theory (with Donn) for climatic change.

In association with Frank Press and Wenceslas Jardetsky, Ewing launched a major era of seismology with the study of surface wave dispersion, explaining many previously misunderstood features of seismograms. The book Elastic Waves in Layered Media by Ewing, Jardetsky and Press served as a basic text for a new generation of seismologists.

Thus. Ewing's career was one of many thrusts into the unknowns of the Earth: the Continental Shelf, submarine ridges and trenches, the structure of continents, ocean basins and the earth as a whole, the structure and origin of sediments and the structure of the oceanic water column. He certainly provided plenty of stimulating competition for other oceanographic laboratories.

The development of the theory of ocean floor spreading and plate tectonics was made possible to a great extent by the observations made by Ewing and his coworkers. The dis-

covery of the thinness of the oceanic crust and oceanic sediments and the discovery of the continuity of the midoceanic ridge system were especially important keys. Ewing enthusiastically supported the JOIDES drilling programme which was to give dramatic confirmation to the concept of ocean floor spreading. He maintained a healthy scepticism for any new schemes proposed either by himself or others and the theory of the new global tectonics was no exception. He was later to comment that he was amazed to see so many of the facts that had puzzled him about the oceans explained by such a simple theory.

Ewing was a man of quiet courtesy, which belied a singlemindedness of purpose. Once the priorities were set, nothing would be permitted to get in the way. Thus, he would turn the lathe in the ship's crammed machine shop all night to replace a faulty gear. Once when swinging gravity pendulums aboard submarines, he told one of us: "If we get sub time, no matter where or when, Worzel or I will be aboard" While securing some explosives aboard the VEMA during an early morning gale, Ewing and two shipmates were washed overboard. Ewing and one man were miraculously saved but Ewing sustained injuries from which he never quite recovered. In reflecting upon his own reactions, Ewing characteristically assigned his priority: to stay affoat.

During his long and productive career, he helped train more than 200 graduate students. Affectionately known to his students as 'Doc', he expected no less from them than the hard work and devotion that he himself was always ready to give. His students and colleagues will remember the many times they stepped from his office inspired. and challenged by either a few minutes or a few hours of intense interaction. He was the author of more than 300 papers and many honours came to him: among them, election to the National Academy of Sciences in 1948, the Vetlesen Prize in 1960, Foreign Membership of the Royal Society in 1972. and also the National Medal of Science in 1973.

His last two years were spent very happily as Green Professor of Marine Sciences and Founding Chief of the Earth and Planetary Sciences Division of the University of Texas Marine Biomedical Institute in Galveston.

## **Announcements**

#### Awards

Philip S. Corbet has been awarded the Gold Medal Award of the Entomological Society of Canada.

The Fondation de Physiopathologie Professeur Lucien Dautrebande Prize has been awarded to Professor Durrer for his contribution to clinical and electrophysiological knowledge of the heart

Judah H. Quastel, Hans J. Müller-Eberhard, Hector F. DeLuca, Roger Guillemin, Andrew V. Schally, David Baltimore and Howard M. Temin are recipients of the 17th Annual Gairdner Foundation Awards.

Robert Allan Smith has been made an honorary Commander of the Order of St:Olav, the Royal Norwegian order of chivalry.

#### **Appointments**

James Barron Bridges has been appointed to a second chair of physiology at the Queen's University of Belfast.

Philip John Randle has been appointed to the chair of clinical biochemistry at the University of Oxford.

Malcolm Rowland has been appointed to the additional chair of pharmacy at the University of Manchester.

#### Miscellaneous

The Pharmaceutical Manufacturers' Association Foundation Medical Student Fellowships. Four one-year grants for the academic year beginning July 1, 1975, will be awarded to candidates interested in research and teaching careers in pharmacology/clinical pharmacology.

The Foundation will also award twoyear postdoctoral fellowships in pharmacology/morphology. For information contact: Thomas E. Hanrahan, Pharmaceutical Manufacturers' Association Foundation, 1155 Fifteenth Street, N.W., Washington DC 20005.

Maltwood Fund for Archaeological Research in Somerset. The Royal Society of Arts invites applications for grants in aid of archaeological research to be carried out in the county of Somerset during 1975. For further information contact: J. S. Skidmore, Royal Society of Arts, John Adam Street, Adelphi, London WC2 6EZ.

#### International meetings

December 9, Imaging by Holography, London (R. J.; Neville, Research Division, Kodak Ltd, Headstone Lane, Wealdstone, Middlesex).

December 11-13, Surface Analysis, Slough (D. Nicholas, Head of Analytical Services, Fulmer Research Institute Ltd, Stoke Poges, Slough SL2 4QD).

December 22, Ethics in an Age of Pervasive Technology, Israel (Dr Mordechai Levy, Senate Building, Technion Haifa, Israel).

January 3, Elucidation of Important Mechanisms for Controlling Cellular Integrity, London (Dr D. J. G. Davies, School of Pharmacy and Pharmacology, Claverton Down, Bath BA2 7AY).

January 6-8, The Mechanics and Physics of Fracture, Cambridge (Meetings Office, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX).

January 6-9, Geophysics and Cosmology of Solar System Observables, (Dr Newcastle-upon-Tyne F Stephenson, School of Physics, University, Newcastle-upon-Tyne NE1 7RU).

January 10, Phase Equilibria and Phase Separation in Polymer Systems, Essex (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X-8QX).

January 21-22, Power Plants and Future Fuels, London (The Secretary, The Institution of Mechanical Engineers, 1 Birdcage Walk, London WC2R 3LF).

#### UNIVER Y OF LEICESTER

DEPARENT OF GENETICS (Head of Departn: Professor R. H. Pritchard) Applicatione invited for a post of

#### CTURER

The person anted will participate in the teaching of genetito both medical students and those studying for B.Sc. in Biological Sciences. Candidates must ave a broad knowledge of genetics and prefere will be given to those who combine this withistdoctoral experience in some aspect of nucleic d technology.

Initial salary aciding to qualifications and experience within thrange £2,118 to £4,896 a year plus threshold paients, at present £167.04, plus Superannuation. There particulars from the Registrar, to who applications should be sent quoting reference. G by January 5, 1975. (1986)

#### THE DEPARTENT OF PSYCHOLOGY PRINCETO UNIVERSITY

anticipates several openings for the 1975-76 academic year. On is at the Full Professor level in social psycholog, where we seek an addition to our ongoing pigramme in social psychology. The other(s) at the Assistant Professor level are in general experimental psychology, with concentration in animal behaviour developmental and comparative psychology of personality research. These latter anticipated opinings are not rigidly tied to any specific area of expertises. Sheer excellence in research and teachig will override area-of-interest considerations.

Nominations and applications should be sent to

considerations.

Nominations and applications should be sent to the Chairman, Deprtment of Psychology, Green Hall, Princeton University, Princeton, New Jersey 08540. We are an equal opportunity employer with a vigorous affirmative action programme. (2022)

## **Senior Pharmacologist Anti-Inflammatory Research**

Applications are invited for a senior post in our Pharmacology Department in Welwyn Garden City, Hertfordshire. The department is responsible for carrying our research and screening work aimed at the development of new drugs in which the pharmacologists participate in the research programmes of interdisciplinary groups.

The senior pharmacologist we appoint will be responsible for directing the work of a team of pharmacologists engaged in anti-inflammatory research. Applicants should have a Ph.D. qualification and preferably some post-doctoral experience in anti-inflammatory research.

Our Pharmacology Department is located in new laboratories where the facilities and working conditions are excellent. Conditions of service are above average and in appropriate cases generous assistance with relocation will be available.

Roche Products Limited is part of a major international pharmaceutical firm based in Switzerland and is itself one of the leaders in the industry in the United Kingdom. If you would like to apply for this post please write for further information, and a Company booklet, to the Welwyn Personnel Manager.

Closing date for applications, December 13, 1974.

Roche Products Limited Welwyn Garden City Hertfordshire AL7 3AY

#### INSTITUT MAX VON LAUE-PAUL LANGEVIN GRENOBLE—FRANCE

The Institut Max Von Laue-Paul Langevin operates a high flux reactor providing intense beams of neutrons for studies of condensed matter in the fields of physics, chemistry, biology and materials science. Visitors from universities and research centres in the member countries, France, Germany and the U.K., and resident scientists use the high flux beam reactor and the Institut provides scientific and technical support.

Applications are invited for the following post at Grenoble:

### ENGINEER FOR REACTOR OPERATION (MECHANICAL ENGINEERING GROUP)

The successful applicant will be in charge of a group responsible for the maintenance of and adjustments to the mechanical equipment of the reactor and associated facilities.

Applicants should possess a degree or equivalent qualification and have a sound knowledge of reactor operation and of the behaviour of materials subjected to radiation. A working knowledge of French is desirable but not essential, as tuition will be given.

Salary will be according to qualifications, experience and responsibilities. Removal expenses will also be paid and assistance given in seeking accommodation.

Write for application form to: Mr. D. McConville, Science Research Council, c/o British Rail Engineering Ltd., Swindon Works, Swindon, Wiltshire, SN1 5BW, quoting reference and post applied for.

Completed application form should be returned by December 16, 1974. Ref: ILL/05.

#### MEDICAL RESEARCH COUNCIL CLINICAL AND POPULATION CYTOGENETICS UNIT SCIENTIST

A vacancy exists in the Experimental Studies Section of the above Unit for a research scientist, who will be principally concerned with the genetics/cytogenetics of human/mutine hybrid cells, with emphasis on the mapping of human genes by somatic cell hybridization.

The minimum qualification is an honours degree 2(1) in a biological science, although preference will be given to applicants with a Ph.D. or equivalent postgraduate experience. Previous experience of mammalian cell culture would be an advantage, but is not essential. Salary, dependent upon age, qualifications and experience will be on a scale £2,019 to £3,636 or £4,896 with F.S.S.U. benefits.

Applications in writing by December 16, 1974, giving full personal particulars and names of two referees, to the Administrative Officer, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, (2002)

#### INSTITUT MAX VON LAUE—PAUL LANGEVIN GRENOBLE\_FRANCE

The Institut Max Von Laue—Paul Langevin operates a high flux reactor providing intense beams of neutrons for studies of condensed matter in the fields of physics, chemistry, biology and materials science. Visitors from universities and research centres in the member countries, France, Germany and the U.K., and resident scientists use the high flux beam reactor and the Institut provides scientific and technical support.

Applications are invited for the following post at Grenoble:

#### ENGINEER FOR THE REACTOR

The successful applicant will assist the Head of the Reactor Department on problems of safety and will also provide assistance to all the Section Heads in the Department on studies required to improve the reliability and safety of the reactor. His duties will also include liaison with the French nuclear authorities. Applicants should possess a degree in engineering or equivalent, qualification and have had considerable experience on the operation and safety of nuclear reactors and in writing safety reports. They should also have a working knowledge of French.

Salary will be according to qualifications, experience and responsibilities. Removal expenses will also be paid and assistance given in seeking accom-

Write for application form to: Mr. D. McConville, Science Research Council, c/o British Rail Engineering Ltd., Swindon Works, Swindon, Wiltshire, SN1 5BW, quoting reference and post applied for.

Completed application form should be returned by December 16, 1974. Ref: ILL/04.

#### DEPARTMENT OF PE UNIVERSITY OF A ELECTRONMICROST

Applications are invited for ant Professor in the area of Electronmt. Exceptional candidates in other areas deed state physics will be considered. Thesed state group at the University of Alberts of eight members in a Physics Departm forty-two faculty members.

The effective date of appoint April 1, 1975. The closing date for applic February 1, 1975.

#### THE PRMACEUTICAL SOCIETY: GREAT BRITAIN

JOURN OF PHARMACY AND ARMACOLOGY

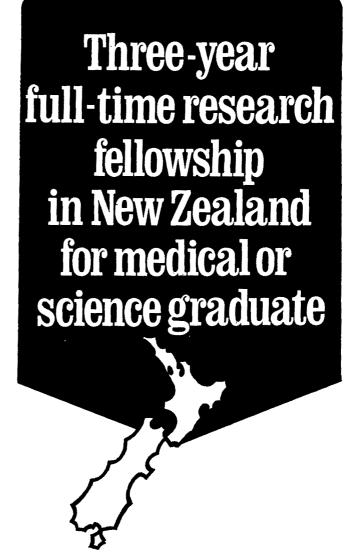

## EDFORIAL **ASISTANT**

The position assistant in the Editorial Department of Journal of Pharmacy and Pharmacology shortly to become vacant. The Journal lishes research papers and reviews on the originating in the disciplines associa with the pharmaceutical and medical spees. The editorial department is unusual being concerned with both editorial and district associations. editorial and pishing procedures.

The person abinted will assist the Editor and will be offd training in all aspects of the duties, whi include the preparation of texts for publicon, library research, proof reading, indexir diagram presentation and liaison with pter and publisher. Salary according to at and experience will be in the range of £538 to £3,024 p.a. (under

Graduates in harmacy or in an allied science who has an interest in the presentation of technal information are invited to apply. Any itential applicant wishing to know more abot the Journal will be a recent copy of request (Telephone 01-405 8967, Ext. 24.)

Details of eduction, qualifications and experience should e sent to the Secretary and Registrar. The Pharmaceutical Society of Great Britain, 17Bloomsbury Square, London WCIA 2NN, in an envelope marked "Appointment J.P.P. (2039)

The Council of the Wellington Medical Research Foundation Inc. invites applications for the whole-time position of Malaghan Research Fellow to be held at Wellington Hospital and/or at Victoria University of Wellington.

The applicant should be a research worker with evidence of

capacity to undertake original research. He must possess a higher qualification such as Ph.D. or Membership of a Royal College of Physicians, or Pathologists. He should indicate an intended research project on which he has embarked or is dedicated to pursue. Whilst the Council will accord preference to an applicant whose project is in the field of Haematology, projects in other fields of medical research pertaining to diseases of the blood will be considered.

The yearly rate of salary shall be as agreed upon between the selected applicant and the Council of the Foundation. It will be within the scale for Specialist Medical Officers, which is \$12,639-\$16,926,\* or for Science Graduates with Ph.D., \$7,601-\$11,774.\* Adjustments will also be made to cover increases in the cost of living in line with Wage Adjustment Orders covering Hospital or University staff.

The appointment is for three years. Assistance towards transport expenses is available.

Conditions of Appointment, method of application and other information may be obtained from the Secretary of the Foundation in New Zealand, or from the Office of the High Commissioner, New Zealand House, London.

Applications close with the Secretary of the Foundation on 28th February, 1975. \*(N.Z. Dollars)

## **WELLINGTON MEDICAL RESEARCH FOUNDATION INC.**

P.O. BOX 3025 WELLINGTON NEW ZEALAND

## PRINCIPAL PHYSICIST

Required for

#### KING'S HEALTH DISTRICT

and

#### S.E. THAMES REGIONAL HEALTH AUTHORITY

Applications are invited for the above appointment in the Department of Medical Physics, King's College Hospital, with some responsibilities in other hospitals of the Region. The successful applicant will have had wide experience in medical physics, and will be responsible to the Director of the Department for such work of the Department involving ionizing radiation as may be agreed. This work may include physics in Radiotherapy, Nuclear Medicine and Radiation Protection at King's College Hospital and Medical School, Nuclear Medicine Physics at the Brook Hospital, Woolwich, and Radiation Protection in more than 60 hospitals in the S.E. Thames Region.

The Department of Medical Physics is attached to King's College Hospital Medical School and University of London, and the successful applicant will take part in the research and teaching activities of the Department.

Further information and application forms from the Personnel Office, King's College Hospital, Denmark Hill, London SE5 9RS.

Tel: 01-274 6222 Ext: 2724/8.

Closing date December 16, 1974.

(2037)

#### UNIVERSITY OF ZAMBIA

Applications are invited for the following posts in the School of Medicine:-

1. PROFESSOR AND SENIOR LECTURER AND LECTURER IN DEPARTMENT OF SURGERY.

OF SURGERY.

Candidates must possess a recognised postgraduate qualification in Surgery. Professorial candidates must have distinguished themselves in a field of Surgery and have several years experience of teaching and administration in a University. A detailed list of scientific publications is required from all candidates as well as a full statement of educational and professional training and positions held. Appointee to Professorial post will be expected to head the Department of Surgery while appointees to the Senior Lectureship will act as Consultant and Senior Registrar, respectively.

2. PROFESSOR/SENIOR LECTURER IN DEPARTMENT OF PATHOLOGY AND MICROBIOLOGY.

Candidates should have specialised in either Basic Immunology or Clinical Immunology or Immunopathology. They should possess a medical degree and an appropriate postgraduate qualification or M.R.C. Path (or equivalent), and adequate experience in the field of Immunology. Non-medically qualified candidates whose basic training is immunology will also be considered.

- 3. SENIOR LECTURER/LECTURER IN BIOCHEMISTRY in Department of Physiological Sciences. Candidates must possess a posterior data and the control of the control logical Sciences. Candidates must possess a postgraduate qualification in Biochemistry and for Senior Lectureship level, teaching experience and a list of scientific publications are required. Appointee will be required to teach third year medical undergraduates and conduct research.
- 4. SENIOR LECTURER/LECTURER IN ANATOMY in Department of Anatomy. Candidates should be graduates with postgraduate qualifications in Anatomy. Preference will be given to those with five or more years experience in undergraduate Anatomy teaching and with interest in the research fields of Cytology and Histochemistry. Appointee will be responsible to the Head of the Department and will be expected to participate in Histology and Medical Embryology teaching of 3rd year medical students.

SENIOR LECTURER/LECTURER IN DEPARTMENT OF CHEMICAL PATHOLOGY.

5. SENIOR LECTURER/LECTURER IN DEPARTMENT OF CHEMICAL PATHOLOGY.

Candidates should be medically qualified and must possess M.R.C. Path or equivalent with relevant teaching and research experience. Non-medically qualified candidates who have experience as Clinical Biochemists will also be considered. Appointee will be expected to teach undergraduate and postgfiraduate medical students, conduct specialist services for the University Teaching Hospital staff and take part in research.

Salary scales: Professor K7,400 to K7,800 p.a. Senior Lecturer K5,600 to K6,600 p.a. Lecturer K4,000 to K5,400 p.a. Medical differential allowances may be payable locally. (£1 sterling=K1.50). The British Government may supplement salaries of married Professors, Senior Lecturers and Lecturers in range £516 to £1,152 p.a. (sterling) or salaries of single Professors and Senior Lecturers in range £78 to £204 p.a. (sterling) (normally free of all tax). This supplementation is unlikely to be applied to single appointees to Lecturer level. These rates are for academic staff, other than clinical medical staff. The rates for clinical medical staff are currently under review. There may also be provision of children's educational allowances and holiday visit passages, family passages; various allowances; superannuation and medical aid schemes; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than December 30, 1974 to the Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia, Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London WIP 0DT. Further particulars may be obtained from either address. (2056)

#### POSITIONS IN GEORY

Scarborough College, Universitanto, expects to make 3 appointments inhy effective July 1, 1975, subject to tolity of funds. Applications in any field ansidered but preference will be given dates with research and teaching interests in:

(i) Economic Geography

## **Oligotrophic Lakes Research Scientist**

Canadian \$15,800 to \$25,600

The ONTARIO MINISTRY OF NATURAL RESOURCES, Fish and Wildlife Research Branch, requires an oligotrophic lakes research scientist to devise, direct and participate actively in research and experimental management to develop and apply effective methods of assessing stocks and allocating surplus yields in the multi-gear, multi-species, multi-agency fisheries of Lake Superior and related waters; contribute new understanding of aquatic production systems by participating in multi-disciplinary research in systems ecology. Location: Maple, Ontario, Canada (approximately 20 miles from Toronto.)

Qualifications: Ph.D with solid training in applied mathematics and statistics, biometrics and systems ecology; experienced in the use of computers as well as in biology preferable; specialization in fisheries preferable, but not necessary; extensive experience in field and laboratory work, preferably in multidisciplinary research teams; published contributions earning international recognition.

Please submit detailed resumes by December 31, 1974, to:

Recruitment Officer, Resources Branch, File NR412, Civil Service Commission, Parliament Buildings, Toronto, Ontario, M7A 1Z5, Canada.

This position is open equally to men and women.

**Ontario** Public Service (2041)

## **ENTOMOLOGIST**

Chesterford Park is the Research and Development centre for Fisons Agrochemical Division, responsible for the invention, selection and development of novel chemical compounds for the protection of crops, public health and materials. Internal transfers have created two immediate vacancies for Entomologists in our Zoology Department.

Entomologist

The duties of this post will be to conduct and evaluate both laboratory and field trials of candidate new pesticides (insecticides, acaricides and nematiwhich may overseas duty for periods of up to six months in any one year. After suitable training, full responsibility will be given for specific departmental projects. Applicants will probably be in the age range 24 to 28, with a good honours degree in Zoology/Entomology or Applied Biology, and have some post graduate experience of Applied Entomology and a sound know-Entomology and a sound know ledge of laboratory and field working experimentation. knowledge of French, German or Italian would be advantageous, (Ref. No. 671/197).

Senior Entomologist

The successful applicant would be closely involved with the planning and execution of applicant the annual trials programme of candidate new pesticides, for which it is envisaged he would

ultimately assume total responsibility. The preferred upper age limit is 35 and candidates should possess a good honours degree in Entomology (Ph.D. is not essential) with several years post graduate experience of Applied Entomology, a thorough knowledge of laboratory and field techniques of pesticide evaluation and preferably a specialised knowledge of these. Considerable travel, both within the U.K. and overseas is likely to be involved. (Ref. No 674/197).

Starting salaries will be competitive and in accordance with career record to date. Other company conditions of employment include a first class pension scheme, a generous sick pay scheme, profit sharing bonus and four weeks leave (after one year's service). Assistance with relocation expenses will be available where appro-

# Graduate

Shell Research Limited, at their Sittingbourne Research Centre in Kent, have a vacancy for a graduate chemist, specialising in organic mass spectrometry, to work in the Physics Division of the Milstead Laboratory of Chemical Enzymology. You should have a PhD and preferably some post doctoral experience, under a recognised authority, in the field of mass spectrometry. You will join a team providing an analytical service to the Sittingbourne Research Centre and act as a consultant to other locations on site which operate their own glc-mass spectrometers. Full support services are available but there will be some opportunity to carry out independant research which will actively be encouraged. The job offers exceptional facilities for research in the field of mass spectrometry. At present the instruments available consist of a MS30 double beam, double focusing mass spectrometer coupled to a gas chromatograph; a MS902 double focusing mass spectrometer which currently is being equipped with facilities for chemical ionisation and field ionisation/field desorption; and a VG2040 data handling system. The level of appointment will depend on background and experience and the salary offered will be competitive. Please write giving details regarding personal background and experience or write/telephone for an application form to: Shell Research Limited, Recruitment Division (N), PNEL/34, Shell Centre, London SE17NA. Telephone 01-934 2948.

### UNERSITY OF NEWCASE UPON TYNE ORGANIC OCHEMISTRY UNIT Applications invited for the post of SENIOR REARCH ASSOCIATE (£2,0 to £3,285)

### RESEARH ASSOCIATE (£2, 8 to £2,412)

in the ORGANIC EOCHEMISTRY UNIT for research within theireld of organic geochemistry and petrology of ecent and fossil sediments, including coals.

including coals.

The Unit is with the Department of Geology and the post would e suitable for candidates with a background of gelogy or chemistry or preferably both. In the first instance the post is available until Aril 30, 1976, commencing January 1, 1975, is by arrangement. Starting salary will be accoding to age and experience. Applications including a brief curriculum vitae and the names of two referees should be sent as soon as possible to: Dr. D. G. Murchison, Organic Geochemistry Unit, The University, Porter Building, St. Thomas St. Newcastle upon Tyne NEI 7RU.

# Microbiologist/ Fermentation Technologist

The R & D Division of G. D. Searle & Co. Ltd., a worldwide ethical pharmaceutical organisation, has an opening for a graduate to join a department working on the growth and physiology of tissue culture cells. The candidate would initiate research into novel methods of growing cultured mammalian cells and would develop this work to pilot plant scale. Excellent laboratory and pilot plant facilities are available for this project.

The post would ideally suit a good honours graduate in microbiology or related subject with an interest in fermentation technology. Previous experience is desirable but not essential.

An attractive commencing salary will be offered and conditions of employment include 4 weeks' holiday, Pension Fund Scheme, BUPA Scheme, Staff Restaurant and an active recreation club. Assistance with relocation expenses will be given in appropriate circumstances. Initially, please contact: H. W. Čooke,

Personnel Manager, R & D Division, G. D. Searle & Co. Ltd., Lane End Rd., High Wycombe, Bucks. Telephone: High Wycombe 21124 Ext. 3283. Please quote Reference: RA/118.

(2079)

## Administrative Assistant

We have recently appointed a Project Manager to be responsible for many of the long-term toxicological studies carried out in the Laboratory. He needs a graduate assistant with biological knowledge and secretarial training. The assistant's main duties would be:assisting with long-term planning, arranging and minuting project meetings, ensuring that relevant toxicological information is available to project teams, acting as a communication link between the Project Manager, scientists and ICI Divisions, collecting, assembling, sub-editing and issuing toxicological reports and acting as a personal secretary to the Project Manager.

This will be an interesting and challenging appointment in a newly-formed Group.

Applications and enquiries should be addressed to:-

Miss A. Waring, Personnel Officer, Imperial Chemical Industries Limited, Central Toxicology Laboratory, Alderley Park, Nr. Macclesfield, Cheshire SK10 4TJ.

Tel: Alderley Edge 2711 Ext 156.

(2086)

MINISTRY OF AGRICULTURE, FISHERIES AND FOOD Fisheries Laboratory Burnham-on-Crouch

# RINE ECOLOGIST

HIGHER SCIENTIFIC OFFICER to carry out fundamental research on bethos/sediment relationships in support of a team carrying out routine ecological investigations related to pollution around the coast of England and Wales. The study will involve field work in coastal situations and trips to sea in research vessels.

The appointment will be for period of three years during which the applicant will be required to complete a specific programme of investigations under the general direction of the project leader.

QUALIFICATIONS: A 1st or 2nd class honours degree and have at least 3 years postgraduate research experience preferably benthic ecology or in a related subject. Ability to work at sea essential.

AGE: Under 30.

SALARY: £2,461 by 8 increments to £3,371 p.a., also threshold increases. Short-term gratuity.

APPLICATION FORMS are available from Mr S. A. COLLINS, Ministry of Agriculture, Fisheries and Food, Room 504, Victory House, 30-34 Kingsway, London WC2B 6TU. Telephone No. 01-405 4310 Extn 20 and 21.

Closing date for completed applications: December 20, 1974.

# **Biochemists**/ **Chemists**

Applications are invited from graduates in biochemistry or chemistry to fill two vacancies at the Laboratory. The successful applicants will be required to assist in solving problems concerning the biochemistry and physiology of (a) pesticides and herbicides and of (b) novel food supplements in mammals.

We would like to appoint people with 2 or 3 years experience in such work but would consider applications from recent graduates.

Applications and enquiries to:-Miss A. Waring, Personnel Officer, Imperial Chemical Industries Limited, Central Toxicology Laboratory, Alderley Park, Nr. Macclesfield, Cheshire SK10 4TJ.

Tel: Alderley Edge 2711 Ext 156.

### **Pharmacologist**

Reroducts Limited is the United Kingdom subsidiary oge and successful pharmaceutical company, with a law Research Laboratory in our Welwyn Garden City, Hishire, site.

Wseeking a graduate with relevant experience to join a working in the field of neuropharmacology. The perpointed should have a B.Sc. in physiology or phology and since graduation should have become falwith electro-physiological techniques.

Ouratories provide facilities and working conditions of a vgh standard; in addition we can offer Conditions of Sewhich are attractive, including generous assistance wification expenses in appropriate cases.

Apions for this post quoting reference RD should be add to the Welwyn Personnel Manager. Closing date Deer 20, 1974.

Roche Products Limited elwyn Garden City, Hertfordshire AL7 3AY

FELLOWSHIPS AND STUDENTSHIPS

### TE UNIVERSITY OF MANCHESTER **IPARTMENT OF CHILD HEALTH**

### CINICAL RESEARCH **FELLOWSHIPS**

The optimity arises of awarding two Clinical Research Fellowships to join a fulime research team within the Department of Child Health. The main, but of exclusive interest of the team has been the development of the brain id its vulnerability, with an emphasis on the long term sequelae of environmental influences during fetal life and infancy. The present aim is that climans preparing for a career in a University Clinical Department should he to extend the work of the present team into the clinical area; and this dild be in Paediatrics, Obstetrics, Developmental Behavioural Sciences, evelopmental Pathology, Epidemiology, or any other field of clinical releance to the team's central interest. Appointments are likely to be at the ost-M.R.C.P., Registrar/Senior Registrar level, and should lead to a highe Degree. Enquiries to Professor John Dobbing, The Medical School, Stoford Building, Oxford Road, Manchester M13 9PT. Tel: 061-

### LIVERPOOL POLYTECHNIC SCHOOL OF PHARMACY SRC STUDENTSHIP IN MEDICINAL CHEMISTRY

Applications are invited from candidates with a good honours degree in Pharmacy or Chemistry, or Grad. R.I.C. to work for a Ph.D. degree on the project "4-phenylpiperidine derivatives as potential non-addicting analgesics". The work will involve organic synthesis and stereochemical Audies

The Project is a C.A.S.E. award and the co-operating body is Allen and Hanburys Ltd. The S.R.C. stipend applies and this may be supplemented by payment for teaching duties and income during the industrial period.

Enquiries and applications to A. F. Casy, D.Sc., F.P.S., School of Pharmacy, Liverpool Polysechnic Byrom Street, Liverpool L3 3AF, Tel: 051-207 3581.

### BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH 1975

Notice is hereby given that an election Junior Fellows to begin work on October 1, 1975 will take place in May 1975. Junior Fellowships have annual values within the range of £2,000 to £2,525 p.a. (plus London Allowance £213 p.a.) plus yearly increments of £175 for 3 years. As a superannuation benefits are provided for which the successful candidate will be required to contribute 61% of the animal stipend and to which the Trust will make a contribution of 12% Fellows who are already members of the Federated Superannuation System for University or of the National Health Services Superannuation Scheme may opt to remain in their existing scheme, which case the contributions will be at the rates appropriate to them. Candidates must have taken a degree in a faculty of a university approved by the Trustees in Her Majesty's Dominions, Protectorates and Mandated Territories, India, Pakistan, the Republic of Ireland and the United Kingdom, or a medical diploma registrable in the U.K. Elections to Junior Fellowships are rarely made above the age of 35 years. Applications from candidates must be received not later than March 21, 1975. Candidates must submit evidence that they can be given accommodation in the departments where they propose to work, which must be in Great Britain or Ireland.

Forms of application and all information may be obtained from Professor W. G. Spector, Pathology Department, St. Bartholomew's Hospital, London ECIA 7BE. For overseas candidates forms of application may be obtained from The Secretary, South African Medical Council, P.O. Box 203, Pretoria, South Africa; The Ministry of Health, The Government of India, New Delhi, India; The Secretary, Dept. of Education and Science, P.O. Box 826, Canberra City, A.C.T. 2601, Australia; The Dept. of Health, Weilington, New The Canadian Medical Association, Alta Vista Drive, Ottawa 8, Ontario, Canada

### UNIVERSITY OF ST. ANDREWS DEPARTMENT OF GEOLOGY **BURMAH RESEARCH FELLOWSHIP**

FELLOWSHIP

Applications are invited for a fellowship supported by the Burmah Oil Company. The Fellow would be expected to initiate and sustain a project on the Solubility of hydrocarbons in water in a sedimentary environment in the Department of Geology. He should have had post-graduate experience in organic geochemistry and hold at least the degree of M.Sc. The appointment will be for free years in the first instance with a possible extension for a further two years. Salary scale £1,791 to £2,412 plus F.S.S.U and threshold arrangements.

Further information may be obtained from Professor E. K. Walton, Department of Geology, University of St. Andrews, Applications with the names of two referees should be sent to the Establishments Officer of the University, College Gate, St. Andrews, Fife, by December 31, 1974. (2063)

### CSIRO

### **AUSTRALIA**

# DIVISION OF PROTEIN CHEMISTRY

PARKVILLE, VIC.

### POSTDOCTORAL FELLOW

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

### FIELD

### PROTEIN CHEMISTRY

GENERAL: The Division of Protein Chemistry is located in Parkville, close to Melbourne University, and has a research staff of around sixty scientists. A wide range of physical techniques is available in the Division including an analytical ultracentrifuge; u.v., i.r. and fluorescence spectroscopy; e.s.r., n.m.r. and mass spectrometry; flash photolysis; spectropolarimetry. Comprehensive on-site computer facilities are also available. The research programme is concerned with the structure and chemistry of both animal and plant proteins but particular emphasis is given to the proteins of the wool fibre. Three distinct classes of proteins have been isolated from wool and representatives from each class have been purified and sequenced. During biosynthesis the wool proteins aggregate and interact in specific ways to form ordered fibrous assemblies which ultimately constitute the wool fibre.

**DUTIES:** To carry out a study of the properties of wool protein derivatives in aqueous solution and to search for evidence of specific interactions between proteins of the same class and of different classes. Purified proteins are available for this study and preliminary studies have shown that strong interactions occur.

**QUALIFICATIONS:** A Ph.D. degree, or equivalent qualification, in an appropriate discipline together with a demonstrated ability for original research. Experience in the fields of physical chemistry or physical biochemistry would be advantageous.

SALARY: The appointment will be made within the ranges of Research Scientist or Senior Research Scientist: \$A10,778 to \$A16,187 p.a.

TENURE: The position is available for a fixed term of three years.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 462/393, should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64–78 Kingsway,
LONDON WC2B 6BD

\*by December 27, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(2068)

# UNIVERSITY OF DEPARTMENT ANIMAL PHYSIC AND NUTRIT

Applications are invited fest of part-time RESEARCH FELL(tk on an A.R.C. funded project cone control of secretion of the gastr hormones and their significance iology of bovine milk fever.

Salary pro-rate on the 18 to £2,757.

Further particulars and at forms from the Registrar, The Unit Ledds, LS2 9JT, quoting reference 1/1/D. Closing date for applicatio-cember 2062)

### AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

### RESEARCH FELLOW-PARTMENT OF ENVIRONMENTAL BIOLOGY

A rellowship is available for research it one or both of the following areas:

(a) Plects of stomatal physiology; (b) Physiological ecology of stomatal behaviour. Applied have a Ph.D. in plant physiology or ecology and an interest in the appliciphysics and mathematics to biological problems. The appo. will have opport co-operate with staff working on related topics in physiology and tothe supervision of Ph.D. scholars.

Englid be addressed to Dr I R. Cowan, Department of Environmental Biological Sciences in the University.

Clos January 10, 1975.

JOHN CURTAIN SCHOOL OF MEDICAL RESEARCH

### ESEARCH FELLOW (ORGANIC CHEMIST)-DEPARTMENT OF PHARMACOLOGY

Applil be expected to have research experience in the chemistry of centrally active ds such as amino acids and/or alkaloids. Excellent facilities are available for organicy within the Department (Head: Professor D. R. Curtis, FAA, FRS), and collaborancouraged with the Medical Chemistry Group of the John Curtain School of Medarch and with members of the Research School of Chemistry. The successful applicatecome part of a multidisciplinary group investigating synaptic transmitters in the fan central inervous system. in the ran central nervous system.

Enquald be addressed to Dr G. A. R. Johnston, Department of Pharmacology

ClosirJanuary 17, 1975.

### RESEARCH SCHOOL OF PHYSICAL SCIENCES

### OR RESEARCH FELLOW/RESEARCH FELLOW/ DOCTORAL FELLOW IN THEORETICAL PHYSICS

The Lent of Theoretical Physics has an academic staff of 15, headed by Professor K. J. Ltur, FAA. The department conducts theoretical studies on nuclear structure and reactionmentary particles, statistical mechanics, solid state physics and plasma physics, hese appointments preference will be given to applicants interested in statistical nuclear physics. It is intended to make two appointments, one as soon as f and another in September 1975; Shorter than normal tenure of appointment as Senioarch Fellow or Research Fellow would be considered for a person on leave from anostitution.

Closing January 6, 1975.

### OR RESEARCH FELLOW/RESEARCH FELLOW-MACROPARTICLE ACCELERATOR GROUP. **DEPARTMENT OF ENGINEERING PHYSICS**

The poliryolves research in high velocity, heavy current, sliding electrical contacts in a matrice acceleration program using unique facilities which include a large homopolaerator (capacity 560 Megajoules, 1.6 million amperes, and power rates of over 50 hatts) to power an inductively driven rail gun employing currents of over 400,000 as and sliding velocities greater than one kilometre per second, to produce acceleratio 10 to 20 gram macroparticles in the range 10,000 to 100,000 gravities. This position isy to interest physicists and electrical and mechanical engineers with a taste for the un

Apart functionarticle acceleration research, work of the Department includes studies in high pelasers, photon physics and laser induced plasmas; plasma physics (tokamak type machand plasma dynamics); solar energy conversion and information science. Facilities able include extensive mechanical and electronic workshops, energy sources and power/amouting facilities. and power imputing facilities.

Successfuplicants should be strongly motivated to contribute to knowledge in the

Closing December 31, 1974.

SALAR (under review): Salary on appointment will be in accordance with qualifica-tions and dience within the ranges: Senior Research Fellow \$A13,163 to \$A15,548 p.a.; Research & and Postdoctoral Fellow \$A9,002 to \$A12,269 p.a.; current exchange rates are aximately \$A=56 new pence; \$USI.31.

OTHER ADITIONS—Tenure: Senior Research Fellow and Research Fellow normally for three yin the first instance with possibility of extension to five years; Postdoctoral Fellow for less than one year and not more than two years.

Reasonabravel expenses are paid and assistance with housing is provided. Superannuation in the F.S.S.U. pattern with supplementary benefits.

The United Reasonabrave the right and to make an appointment or to make an

The Unlifty reserves the right not to make an appointment or to make an appointment invitation at any time.

Prospectivapplicants should write to the ASSOCIATION OF COMMONWEALTH UNIVERSITS (APPTS), 36 GORDON SQUARE, LONDON WCIH 0PF, for further particulars for applying. (2070)

### ALCOHOLISM

### M.C.A. RESEARCH FELLOWSHIP

The Concil offers a Fellowship of 2 or 3 years to a medically or scientificall qualified worker for research into the cause, detection or prevention of alcohol dependence. The financial support will be adjusted to the average of the proposed research. to the experience of the worker and the demands of the proposed research.

Full information from: The Executive Director, The Medical Council on Alcoholism 8 Bourdon Street, London WIX 9HY. (1864)

### **CRYOGENICS RESEARCH** UNIVERSITY OF SOUTHAMPTON POSTD@CTORAL RESEARCH FELLOWSHIP

Applications are invited for the following two year appointment to commence as soon as possible.

### L.N.G. HEAT TRANSFER

To measure 2 phase condensing heat transfer coefficients on large rig at A.E.R.E., Harwell for L.N.G. heat exchangers.

Applicants should have experience in mechanical/chemical engineering or low temperature physics.

Salary in range £2,250 to £2,600 (plus F.S.S.L.).

Applications with names of two referees to the Deputy Secretary's Section. The University, Southampton SO9 5NH. Please quote reference: 254/R/Na.

### SOMERVILLE COLLEGE OXFORD

The Governing Body of Somerville College. Oxford, invites applications from women graduates for a Mary Somerville RESEARCH FELLOW-SHIP, tenable for three years from October 1, 1975, at an annual stipend of £1,280, together with free board and residence in College, Pasticalars and forms of application can be obtained from Miss Harvey, Somerville College, Oxford OX2 6HD. The closing date for applications is January 18, 1975.

### UNIVERSITY OF OXFORD THE QUEEN'S COLLEGE

### JUNIOR RESEARCH FELLOWSHIP IN MEDICINE

The Governing Body proposes, if a suitable candidate presents himself, to elect to a Junior Research Fellowship in Medicine, The Fellowship is offered for research in Oxford in one of the Medical Sciences, such as Anatomy, Biochemistry, Clinical Medicine, Genetics, Pathology, Pharmacology or Physiology. The successful candidate will enter upon his Fellowship on October 1, 1975.

The basic stipend of the Fellowship, which is pensionable under the Federated Superannuation System for Universities, is £1,669 per annum, subject to adjustment in the light of any other emoluments enjoyed by the Fellow. The Fellowship will be tenable for three years and may (but only in exceptional circumstances) be renewed for a further period not exceeding three years. The Fellow will be entitled to free rooms in College (or in approved cases to an increase of stipend in lieu) and to free luncheon and dinner at the Common Table. He may, with the leave of the Governing Body, engage in teaching up to a maximum of six hours weekly.

Candidates must by October 1, 1975, have passed all the examinations required for a first degree at Oxford or another university, and must not have exceeded the thirtieth term from their matriculation. Candidates should apply to The Provost, The Queen's College, Oxford, as soon as possible, and in any case not later than January 6, 1975. They should enclose a statement of their qualifications and of the nature of the advanced study or research they propose to undertake, and should submit any publications or other completed work they wish to have taken into account. They should also give the names of two persons prepared to act as referees. (2091)

### ST. JOHN'S COLLEGE RESEARCH STUDENTSHIPS

The College invies applications for a number of Research Studentships which are offered to men who are no already members of the College but who propose to register as research students at the Utivrsity of Cambridge and become candidates for the Ph.D. Degree in any subject. Tenure of each Studentship will be for three years provided academic progress is satisfactory. Candidates will be expected to have gained, or to have a strong prospect of gaining, a first-class honours degree or its equivalent, and election will be contingent upon satisfactory results in such a final degree examination.

The value of the Studentship will normally be such amount as will bring the Student's total emoluments to £980 a year, in addition to the following payments which will ordinarily be made by the Colege.

(a) approved University and College fees,

(b) allowances for dependants,

(c) a contribution towards expenses of travel from the Student's home.
(d) allowance for periods of approved post-graduate experience.

Enancial assistance may also be given towards the costs of field work, attendance as conferences and other essential expenses.

Students will be expected to apply for State Studentships or other research awards for which they are eligible

An unmarried Student can be accommodated in College during his first year of residence and a married Student will usually be offered accommodation close to the College.

Enquiries should be addressed to the Senior Tutor, St. John's College, Cambridge, CB2 1TB, to whom completed application forms must be sent so as to reach him by April 1, 1975.

# JARANTEED DEMONSTRATION OF COMPRESSION NEUTRONS

### THIS OPTICAL SYSTEMS DIVISION OF KMS INDUSTRIES INC

IS OFFERING FOR SALE, FOR \$8,000,000

A LASER FUSION SYSTEM

The im is able to vary the pulse shape at different pulse lengths. Also included in the tem are the following:—(1) a unique illumination system. (2) a target align focusing system. (3) significant diagnostic equipment including:—

neutron yield ron time-of-flight X-ray yield

integrated, spacially resolved

> emission (target compression monitor)

> spectrum (both line and continuum).

Target ion spectra
Total ion yield
Target coupled energy
Laser optical pulse calorimetry

(both incident and reflected energy).

Target blast wave energy.

KMS JUSTRIES states through its KMS FUSION subsidiary it is offering LASEFISION TARGETS for sale at a price of \$250,000. The price is inclusive of:—

(The right to obtain pellets for three years.

(An initial 10,000 selected pellets from a KMS FUSION catalogue. The customer is allowed certain substitutions among those 10,000 pellets. Additional pellets for sale are at the rate of \$1.00 to \$3.00 each.

### If a cusher acquires:—

(1The KMS OPTICAL SYSTEMS laser fusion system.

(2Pellets from KMS FUSION.

(3Hires KMS INDUSTRIES to take a time and materials management contract for installation services, KMS FUSION will guarantee the demonstration of compression neutrons.

### KMS INUSTRIES is also willing:

- (1 To approve other laser infusion systems which completely meet the KMS FUSION specifications and are approved by KMS FUSION.
- (2) If KMS INDUSTRIES received the installation management contract to guarantee that the specifications continue to be met after installation.
- (3) And if KMS FUSION will guarantee the demonstration of the production of compression neutrons from the KMS FUSION approved laser fusion system.

For furthr information, contact:—

Max Collins, KMS INDUSTRIES INC., P.O. Box 1778,

Telex: 810/233-6022 Tel: 316/769-1100 Ann Arbor, Michigan 48106, U.S.A.

### The Luckham Vibrator VR/4MP

has been designed to meet the increasing use of micro techniques and is ideal for use in mixing liquids, cells and particles. A vibrative action to keep cells and small particles in suspenion, either by using micro-titration plates for small amounts of cells and fluids or small conical flasks where larger quantities are required.

The cells may then be pipetted direct from the vibrator thus saving time and effort of repeated shaking and allowing a continuous quality control to be achieved. The correct speed can be selected, depending on the type of cells or particles being used. Variable speed up to about 3,500 vibrations per minute.

For Full Information please write or telephone.

### ANALYTICAL EMISSION SPECTROSCOPY

JÓZSEF MIKA. Formerly Prof. Metallurgical Chemistry, Technical University of Heavy Industry, Budepest.

TIBOR TÖRÖK. Professor of Inorganic and Analytical Chemistry, University of Budapest. 1974. 530 pp. III. (Cased) £9.00. 0 408 70163 3. Summarises the theoretical foundations of optical emission spectroscopy. Of value to all scientists involved in trace element analysis.

### COMPARATIVE EXPERIMENTS WITH FIELD CROPS

G.V.DYKE, M.A., F.R.S.A., Field Experiments Section, Pothamsted Experimental Section.

1974. 222 pp. III. (Cased) £5.50. 0408 70554 X. This text describes the planning and carrying out of field experiments, and the interpretation of the results obtained.

### THE SOLID STATE: X-RAY SPECTROSCOPY

L.JACOB, D.Sc., Ph.D., F.Inst. Dept. of Physics, University College, Dublin.

1974. 120 pp. III. (Cased) £3.50. 0 408 70625 2. 1974. 120 pp. III. (Limp) £1.75. 0 408 70626 0. This book gathers together the relevant background material necessary for the interpretation of results obtained by the soft x-ray technique.

### STATISTICAL MECHANICS AND SPECTROSCOPY

G. ALLEN, B.Sc., Ph.D., F.Inst. Prof. Dept. of Chemical Physics, University of Manchester.

H.D. PRITCHARD, D. Sc., Pont of Chemistry, Vork

H.D.PRITCHARD, D.Sc., Dept. of Chemistry, York University, Toronto.

1974. 136 pp. III. £1.90. 0 408 70553 1.

Introduces the principles of statistical mechanics and the spectroscopic method simultaneously and in a logical manner,

### **NUTRITION CONFERENCE 7**

Ed.by: H.SWAN, Ph.D., and D.LEWIS, D.Sc., University of Nottingham School of Agriculture. 1974. 220 pp. III. (Cased) £3.75. 0 408 70704 6. These proceedings will be of value to enterprises concerned with the efficient utilization of feed-stuffs, as well as to academics and students in this field.

TRITIUM AND ITS COMPOUNDS 2nd Edition E.A.EVANS, B.Sc., Ph.D.(Lond), D.I.C., A.R.I.C. Assistant Manager, Organic Dept., The Radiochemical Centre, Amersham.

1974. 832 pp. III. (Cased) £18.00. 0 408 70547 1. This will be an invaluable reference tool for organic chemists, biochemists involved in tritium tracer experiments as well as scientists in other disciplines.

### THE SHIKIMATE PATHWAY

E.HASLAM, Ph.D., Dept. of Chemistry, University of Sheffield.

1974. 324 pp. approx. III. (Cased) £9.00. 0408 70569 8.

This text demonstrates the importance of the shikimate pathway and its involvement in the biochemistry of many natural products.

### GLOSSARY OF MOLECULAR BIOLOGY A.EVANS.

1974. 64 pp. (Cased) £2.50. 0 408 70640 6. 1974. 64 pp. (Limp) £1.50. 0 408 70641 4.

A comprehensive guide to the words which are in everyday usage amongst workers in the field of molecular biology,

### COMMUNICATION IN SCIENCE

A.J.MEADOWS, M.A., D.Phil., M.Sc., Dept. of Astronomy & History of Sciences, University of Leicester.

1974. 256 pp. III. (Cased) £6.00. 0 408 70572 8. This book draws analyses of some communication habits of scientists together into a coherent account.

FIBRES Chemistry in Modern Industry Series C.B. CHAPMAN, *I.C.I. Fibres Division*. 1974. 160 pp. III. (Casebound) £2.00. 0 408 70573 2

Provides an elementary introduction to the science of fibres which are produced for use by the textile industry, and for the manufacture of fibre reinforced products.

### Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in Nature. A limit of 300 words is placed on contributions.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. See any contemporary Nature for style, but note:

- (i) To refer to several references by the same author at once, only one reference number need be given.
  - (ii) Cite first and last pages.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-bepublished volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of Nature. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. We are always glad to see artwork for possible use on the cover, whether or not it is associated with a manuscript, but cannot guarantee the return of material.

A fuller guide appeared in Nature (246, 238; 1973).

### Limits to SALT...

EUPHORIA at the news that President Ford had achieved something in the way of a step forward in arms control during his recent meeting with Mr Brezhnev in Vladivostok has been short lived. Although it is certainly encouraging to know that Dr Kissinger has been able to persuade Mr Ford of the importance of keeping SALT high on the list of priorities, the expectations for the next round of talks are likely to be limited and, paradoxically, talk of a long control period (up to 1985) is bad rather than good news. The signs now are that SALT-2 will restrain both superpowers to do only what they intended to do in any case and will allow them ten years before they need to take up the running on limiting arms again.

SALT-2 froze for five years (1972-77) the total number of ballistic missile launchers at 1,710 (United States) and 2,350 (Soviet Union). Of these not more than 710 and 950 respectively could be submarine-based, and the conversion of land-based launchers from 'light' to 'heavy' character was prohibited. The figures were arrived at by little more than an examination of the *status quo* in 1972 and a belief that, if the numbers were disparate, quality made up for quantity. The ultimate in quality was, of course, to put many warheads on each missile, and the impossibility of satellite inspection of MIRVs ruled out any control of their extent.

Two years later the process of MIRVing is proceeding rapidly, with much of the United States fleet both at sea and on land already converted, and Soviet intentions (if lagging) perfectly obvious. Proposals for SALT-2 now include multiple warheads in the list of constraints, not, as far as one can gather, because of dramatic improvements in satellite inspection but presumably because it is considered economically desirable not to go the whole way on MIRVing.

Perhaps the most interesting development, however, is the agreement to trade off concessions. In return for acknowledgement that in SALT-2 strategic bombers will be included in the count of delivery vehicles (an American concession since their bombers out-number Soviet ones 3:1) the Soviet Union will not urge inclusion in the treaty of American forward-based systems. It seems that the total number of vehicles each side will then agree to keep to is about 2,500—a figure that the Soviet Union is already at and that the United States is close to. And 1,300 of these vehicles on each side would be fitted with MIRV, legitimising a total of nearly 2,000 more MIRVed missiles than exist at present!

The quantitative plateau on which both sides will happily take a rest is hardly likely to pose many problems of unemployment for the military-industrial complex. Accuracy and manoeuvrability have long since replaced size as the growth points of the missile field. Undoubtedly the next step is the MARV, or manoeuvrable re-entry vehicle, which can pursue a complex course

to its target, and no doubt sometime in the late 1980s when these have an accuracy of 10 metres or so, the superpowers will start talking about constraints on them.

### ... and UNESCO

Any discussion on the status of Jerusalem is bound to be charged with emotion, and anyone who chooses this particular instant to raise questions of the maintenance of the cultural heritage of the Old City must be assumed to be intent on making the maximum of mischief out of a complex situation. The sponsors, then, of the UNESCO resolution inviting the Director General to cut off assistance to Israel for its 'persistence in altering historical features' and undertaking excavations which endanger monuments 'subsequent to its illegal occupation of the city' were not acting out of purely archaeological concern. Whatever the rights or wrongs of the 'cultural' case against Israel there could hardly have been a more divisive time to raise this issue, and the sponsors. Arab and communist countries, are guilty of hypocrisy if they believe that the rest of the world will see their initiative as other than vulgarly political.

If the sort of moralistic criteria that they are applying to Israel were applied uniformly then Britain should be condemned for retaining the Elgin marbles, the Soviet Union and Czechoslovakia for severe restrictions on academic freedom, the United States for its past oppression of the Indian community and so on. Smart diplomats could rip apart UNESCO within months. But perhaps they need the contributions from the big boys more than they do from Israel.

THE TRANSIT OF VENUS

THE long-anticipated Transit of Venus took place yesterday morning; and already has the first instalment of news from distant observers arrived. The Astronomer Royal has been good enough to inform us that Col. Tennant's observations at Roorkee, India, have been quite successful; too photographs have been taken. He also telegraphs, at the moment of going to press, the gratifying intelligence that the micrometric observations near Cairo and Suez, and the photographic observations at Thebes have entirely succeeded.

At the last meeting of the Astronomical Society the Astronomer Royal gave an account of the final arrangements of the English parties, which do not vary much from those we stated some time ago. i Messrs. Green have arranged for one of their outgoing ships to pass near Kerguelen's Land, with a view of picking up intelligence and telegraphing it from Melbourne.

The southern stations occupied by the American, French, and German parties leave no doubt that the Halleyan method will be extensively employed.

From Nature, 11, 112, December 10, 1874.

### **CETI:** put not your trust in beacons

D. R. Bates, of the Department of Applied Mathematics and Theoretical Physics, Queen's University, Belfast, argues that it would be unjustified to devote resources to the interstellar communication problem on the assumption that there is a neighbouring technological civilisation which continuously operates a beacon signal suited to us.

THOSE active in promoting interstellar communication, for example through the \$10,000 million Project Cyclops, have faith that a neighbouring technologically advanced civilisation, X, would continuously operate a suitable beacon signal that, in addition to showing our civilisation (a technological novice) the star to which to send the acknowledgement signal, would carry other information. Most favour the beacon being omnidirectional because such a beacon by embracing all possible respondents within range, would avoid the contact-time difficulty.

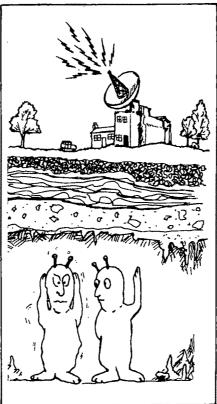

People are heedless to the needs of their descendants as their exploitation of the Earth's resources demonstrates. No terrestrial government would support a costly beacon if it were advised that a response (of debatable benefit) would be unlikely to be received for 200 years. In the case of a government on X, I shall quixotically suppose that the corresponding period is normally 1,000 years. This millennium criterion is a key factor. It would be imprudent for us to incur expenditure on the assumption that X, if indeed it exists, has a succession of governments with a multi-millennium criterion or with a sustained resolve to pass knowledge to alien species on distant planets.

On the millennium criterion the government of X would only finance a beacon if the probable distance to the closest potential respondent were expected to be less than 500 light years. From the spatial distribution of stars it follows that the number of potential respondents in the Galaxy would have to exceed the critical number

$$N_0 \simeq 5 \times 10^4$$

Drake's equation gives 
$$N=RL$$
 (2)

N being the equilibrium number of technological civilisations in the galaxy, R their annual rate of emergence and L their mean lifetime in years. The widely quoted estimate for R, 0.1 per

year, cannot be much too low. It may well be much too high: thus it rests on the dubious assumption that the abundant M and K-type stars are amongst the hosts and on the dogmatic assumption that the unknown probability of life developing on an apparently suitable planet is unity. Young technological civilisations (up to several times as old as us with age measured from the release of nuclear energy) are clearly so few compared with  $N_0$  that they would be dismissed as potential respondents on the millennium criterion.

Some may survive adolescent dangers and conceivably have lifetimes on the stellar evolutionary scale. Perhaps a sufficient fraction do so to make L long enough (at least millions of years) for  $N_c$  to be exceeded. Even granted this, a doubt remains. Ancient civilisations would have explored virtually all of science; they would have sophisticated historical records and rich cultural heritages to study. Many may lose interest in possible signals and even in astronomy, leaving the number in the communicative phase less than required.

Suppose that X has hitherto been isolated. Doubtless signal detection has been thoroughly tried: it has the attraction that its initiators might themselves have the satisfaction of witnessing success. Scientists of X could only

guess the probable distance to the closest potential respondent. Some might ask a government to finance a beacon project. For a government to spend unnecessarily on the basis of a guess would be strange. My quixotic supposition is that it does so provided the project satisfies the millennium criterion. In addition to the costs of constructing the beacon and associated power station the costs of maintaining and replacing them arise. Thought would therefore be given to the length of time for which transmission would be justified.

The number of advanced civilisations within the range of the beacon fluctuates around its equilibrium value. Such civilisations emerge at the annual rate

$$R_{\rm B} = R/N_{\rm C} \simeq 2 \times 10^{-8} R$$
 (3)

which is very slow. Hence the chance of getting a response would not be significantly increased by signalling for the full millennium rather than just for several decades. Several decades would suffice for the beacon to be noticed by any interested advanced civilisation within range and for much information to be carried by its signal (though whether or not this would reach another civilisation would be a dispiritingly open question).

If no replies came by the end of the millennium scientists on X would conclude that no potential respondents were within range. To increase the beacon's range ten-fold would necessitate increasing its power a hundred-fold. Scientists wishing this might attempt to find support for signalling efforts which at best might be acknowledged between 1,000 and 10,000 years later. We would be prodigal to divert resources from promising research on the assumption that they would succeed.

If replies to the first beacon came, the triumph would not make it much easier to persuade a government of X to finance a second. A better case could be made for financing a brief beacon project (covering hitherto unexplored stars) by a government of one of the respondents not already in contact with other civilisations.

Should a communication cell once be established, its radius might expand at a speed comparable with that of light until the entire Galaxy were occupied. For this to be possible the total number of civilisations in the communicative phase would have to exceed  $N_c$ , which is large. Because of the slowness of the emergence rate given

by equation (3), it would be improvident for us to proceed on the assumption that a government of a civilisation belonging to the hypothetical communication network would finance a prolonged beacon project aimed merely at hastening contact with any relatively recently developed civilisation rather than leaving the initiative to the newcomer as the one having the greater incentive and the easier problem.

The inference that it would be irresponsibly optimistic to assume that civilisations operate beacons for more than minute fractions of their lifetimes in the communicative phase has an important consequence. It follows im-

mediately from Drake's equation that relatively few beacons can realistically be expected to co-exist. A proper allocation of research effort cannot ignore that we are hence probably much farther from the nearest beacon than the beacon is from its intended respondents. The acute difficulty this causes is greatly aggravated by another factor.

The communication techniques of a civilisation initially improve rapidly but improvement cannot continue indefinitely. Instead the rate of improvement must decrease and eventually become vanishingly small. Presumably all civilisations which survive long enough

reach a common level of technical attainment, and presumably most beacons are designed by and suited to those at or near this common level. A comparison between Projects Ozma and Cyclops shows strikingly how rapidly our techniques are still improving. The pattern of our development can scarcely be such that Project Cyclops, though far ahead of Project Ozma, is close behind what may ultimately be achieved. Yet, unless the pattern is indeed such, we must be technically much too backward for it to be worth our while engaging in the basically extremely formidable task of searching for signals. 

# international news

PERSISTENT reports of the arrest. torture and execution of doctors and other health workers have been filtering out of Chile ever since Salvador Allende's government was overthrown by the armed forces last year. Although the military junta has consistently denied such charges, most conspicuously in a full-page advertisement in the New York Times, an investigation by three biomedical scientists with support from the Federation of American Scientists (FAS) has now accumulated considerable evidence that left wing members of the medical profession have indeed been a prime focus for particularly brutal reprisals since the junta seized power.

Most of their findings simply back up many previous allegations of brutality, but the report breaks new ground with its analysis of why doctors in particular were singled out for harsh treatment and it also has some disquieting things to say about the Colegio Medico—the Chilean equivalent of the British Medical Association.

First, the Colegio played an active part in Allende's downfall by organising two damaging strikes, one in 1972 and the second immediately before the coup, and it issued two demands for Allende's resignation. After the armed forces seized power and began rounding up Allende's supporters, however, the Colegio did nothing to defend the rights of any of its members, even though its own code of ethics states that it is obliged to defend accused physicians. As Dr Leonard Sagan of the Palo Alto Medical Clinic, who led the investigation, puts it: "the Colegio took almost a brutal delight in the overthrow (of Allende) but it had no compassion whatsoever for its members who were arrested".

### Reprisals against Chilean doctors

by Colin Norman, Washington

In particular, the report notes that one doctor, Carlos Shuster, wrote a letter to the Rector of the University of Chile suggesting that all physicians be classified into three groups "those above suspicion, those with leftish sympathies and those beyond rehabilitation". That letter "seems to have suggested to authorities a general system for classification of health workers into A, B, and C lists", the report suggests, and those lists later served as a basis for arrests and other reprisals.

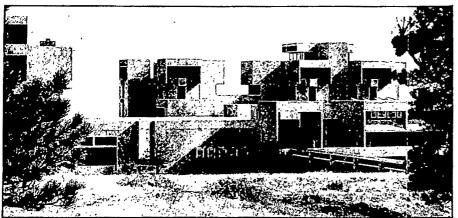

Local responsibility for compiling the lists fell to directors of hospitals and chiefs of service, the report states, and "while we were unable to obtain direct evidence, it seems probable that officials of the Colegio Medico, on the national and local levels, were involved in preparing lists of physicians considered not only dangerous but also politically unacceptable". It adds, however, that only in the Medical School of the University of Chile "did we hear, from the dean, a clear distinction between ideological allegiances and participation in violence. The dean asserted that, at least within his jurisdiction, this distinction has been respected."

Appearance on a list had a variety of consequences. "In some cases it appears that certain physicians were marked for death", the report states; others were arrested and several have been barred from working for the health service—which is tantamount to denying them a job at all.

The investigating team says that it has "good evidence" of 176 physicians who have been suspended from the health service, and it has a list of 109 physicians who had been imprisoned up to June this year. Dr Sagan said last week, however, that the figure for total arrests of doctors is probably nearer 300. In addition, some 250 doctors have fled the country since the country.

As for reports of executions, the team arrived in Chile with a list of 28 doctors believed to have been shot, but several of the reports turned out to have been unfounded. They found good evidence, however, that at least fifteen doctors have died since the coup, and "of those deaths for which we have relatively reliable information, death occurred shortly after arrest in the month of September". The most common excuse given by the authorities was that prisoners were shot while trying to escape, but the report states that such a story is implausible at best.

Finally, the report notes that allegations of torture are widespread, but "are difficult or impossible for foreigners to substantiate in a charged political environment". Nevertheless, the investigating team repeatedly heard two disturbing allegations about the source of the methods of torture used. First, a report that a group of Brazilians were brought to Chile to train the Chilean military was "widely heard" and, second, "there are frequent references to an American training camp in Panama where South American military officers are indoctrinated in techniques of resisting torture, thereby providing technology on the information of torture".

# Trends in meteorology

by John Gribbin

THE National Center for Atmospheric Research (NCAR) in Boulder, Colorado, has just issued its annual report for 1974. The NCAR was set up in 1960, and is run by the University Corporation for Atmospheric Research (UCAR), a private, non profit corporation whose 44 members are universities and other institutions with doctoral programmes in the atmospheric sciences. The operation of the NCAR is supported by the United States National Science Foundation; in practice, this means that the NSF runs the NCAR for the UCAR on a contractual basis. The Center is unique—there are only four other national centres run by the NSF and all of those are centres of astronomy. Indeed the NCAR is itself responsible for the High Altitude Observatory (HAO) but this is not as odd as it might seem, since that observatory carries out research on the physics of the Sun and the solar terrestrial environment, areas of astronomy which seem to have great relevance to problems of the behaviour of the Earth's atmosphere.

Public, and indeed journalistic, attention has focussed on centres like the NCAR lately because of the increased awareness of the problems of climatic change. But as the new annual report shows, this kind of work has been somewhat out of the mainstream of research at the NCAR. That situation may now be changing but more traditional aspects of atmospheric research are clearly still at the forefront as yet.

Topics covered in the past year include research into storm forecasting, the investigation of the interaction of aerosol particles with liquid and ice constituents of clouds, and the airflow and moisture budget of a hailstorm. Some of the work on mechanisms of hail growth highlights just how great the problems of understanding all the workings of our atmosphere are—some theories of hail formation postulate that hail growth begins with the freez-

ing of large supercooled water droplets; others argue that it begins with ice riming around individual ice cyrstals. Studies at the NCAR show that, for Colorado storms, growth from the ice phase is indeed dominant; but Soviet workers report great success with the alternative model. As the authors of the report put it "geographic and en-

### Cloud research

PROFESSOR Jim Megaw, of York University, Toronto, says that as far as man's influence on climate is concerned "the time for descriptive work is past". Like many other people he is greatly concerned about the effect of freon on the ozone layer and believes that its use as a propellant in spray cans should be stopped. Another problem which needs urgent attention is the growth of industrial clouds from the smoke and gas emitted by factories; here, Megaw is at least on the trail of a technique which would make possible the destruction of man's influence on the environment at source.

It seems that laboratory experiments on cloud formation have from time to time been hampered because the 'clouds' refused to form in the cloud chambers. The blame for this has now been laid at the door of the pure ion exchange water used by the experimenters. There is something in ion exchange water which can inhibit the formation of mist, clouds or fog, and it seems very likely that the elusive 'something' is an amine (one of the same family of compounds as those which give fish their characteristic odour). Megaw is now trying to identify the exact compound involved, which is effective in tiny quantities. If it can be pinned down, it could be added to industrial products to inhibit formation of industrial mist and fog. Although Megaw did not mention the possibility of use in aircraft, this would also seem an ideal way to reduce or remove the hazard of increased cloud cover produced by high flying jets.

vironmental differences may provide some explanation of the discrepancy", but if both theories can be correct, depending on circumstances, then a real understanding of hailstorms is far from being at hand.

If that is the case with something as seemingly simple as a hailstorm, the job of those working on climatic modelling might seem impossible. But progress is being made, at the NCAR and other centres. One study of the effect on surface temperatures which might result from changes in stratospheric aerosol or ozone concentrations brought about by operating a fleet of supersonic transport (SST) aircraft seems likely to fan the flames of the SST controversy once more. The effect of the increased stratospheric aerosols on the NCAR model is a reduction in surface temperature by 0.25 K, whereas the effect of the nitrogen oxides emitted by the hypothetical SST fleet is a rise in surface temperature by as much as 1 K. In the first case, increased reflection of solar heat dominates; in the second there is a net increase in absorption. These studies offer no easy solution to the question "is an SST fleet environmentally safe?" but since a change in surface temperature of 0.1 K is considered by the experts to promise significant climatic effects it does seem that the question should at least be asked once again before SST operations begin on a large scale.

Studies of the feedback between temperatures and cloud cover also show how climatologists must solve the chicken-and-egg problem. We hear a lot about how increased cloud cover can cause more reflection of solar heat and a fall in surface temperatures. On the other hand, preliminary results of studies now continuing at the NCAR indicate that there is a positive feedback between changes in surface temperature of the sea and the cloud cover.

The solar studies of the HAO also extend to include work on Skylab, through the Apollo Telescope Mount, and the Executive Director of the NCAR, John Firor, sees studies of the Sun as of increasing importance to problems of climate and atmospheric modelling. Such statistical correlations as there are between solar phenomena (notably the sunspot cycle) and terrestrial weather have not been explained by any satisfactory physical model, but they have encouraged a new look at the solar influence. Indeed, now that the astrophysicists have been forced, by the absence of detectable solar neutrinos, to accept that they do not know all about the workings of the Sun there is room for climatologists to question just how constant the 'solar constant' radiation reaching the Earth is.

research programmes ever undertaken Directors. -the joint French-American explora-Because of a chronic shortage of funds Alvin, which is reckoned to be the best his election statements. of the few research submersibles operated in the United States, would be mothballed.

But last week three federal agencies announced that they have joined forces to keep Alvin operating for at least three years. The National Oceanic and Atmospheric Administration (NOAA), the National Science Foundation (NSF) and the Navy will each put up \$300,000 in 1975. They will renegotiate the funding levels for 1976 and 1977 on an annual basis, but it is estimated that about \$1 million will be found for each of those two years.

The new funding arrangement, apart from being welcome news to Alvin's research crew, is something of an experiment. The NSF has supported Alvin's work in the past on a projectby-project basis, but according to one NSF official, "we would now like to see what the scientific demand will be with a stable funding level". Alvin's scientific programme for next year is now being worked out.

American Chemical Society (ACS) opted for a decisive shift in the ACS's activities when they elected Alan Nixon as the society's president. Nixon conducted a vigorous election campaign (which itself was without precedent in the society's affairs) based on the promise that he would make the ACS more responsive to the professional needs of its members. And he has been followed by two like-minded presidents — Bernard Freidman this panded such activities as manpower cessful sabotage". surveys, public information and Conthe legal expenses of its members who are in dispute with their employers.

# Heavy water shortage faces India

from Narender K. Sehgal

In less than two years' time, India is likely to find her heavy water requirements exceeding availability. So, what's new? Nothing except that, unlike other items, heavy water is a 'nuclear' material and its import from abroad may involve more than mere commercial considerations. (Heavy water is used as moderator and coolant in the Indian nuclear reactors.) In the wake of recent developments following India's explosion of a nuclear device, nuclear powers such as the United States, the Soviet Union and the United Kingdom along with Australia, Canada and West Germany are reported to have decided that no vital 'nuclear' materials shall henceforth be supplied to non-nuclear weapon countries unless they are subject to International Atomic Energy Agency (IAEA) safeguards under an agreement. It is not yet clear whether or not this implies that these countries will refuse to sell heavy water to India. The IAEA meeting at Vienna recently did not provide a clear cut answer.

Work is now in progress in India on three nuclear power projects, one each in Rajasthan, Tamilnadu and Uttar Pradesh. (One of the units of the Rajasthan project is already delivering power. At present, India has a small heavy water plant (14 tonnes annual capacity) at Nangal in Punjab. But four more plants with a total annual capacity of some 300 t are under construction at Kota (Rajasthan), Baroda (Gujarat), Talcher (Orissa) and Tuticorn (Tamilnadu). The production will reach maximum capacity in stages and only by 1978 will it near the 300 t mark-that is, if work goes on as planned.

According to Atomic Energy Commission calculations, India will have to find something like 200 t of heavy water from outside sources during 1976-77 and then again during 1981-83 when shortfalls will occur if no additional production capacity is installed.

In theory, design specifications provide 100% leak-proof heavy-water systems in reactors and after the initial loading (which means more than 200 t of heavy water for each of the reactors under construction in India) no more should be required. But in practice leaks invariably do occur during operation and arrangements are always made to recover the leaked fluid and upgrade it for reuse. However, some replenishing is always needed to make up for losses during the recovery process.

India is reportedly already negotiating with several countries in this con-

nection. If the countries mentioned above choose to enforce their decision, France may be the only alternative left. Then again, the question will hinge on whether or not France will be able to spare the amounts of heavy water required by India, after her own needs are taken care of. If it does not become possible to arrange the needed quantities of heavy water, the already bad power situation will worsen further as the nuclear power projects will either face delays or curtailments in power generation, or both—a price India may have to pay for her two 'sins': conducting a nuclear explosion and refusal to sign the nuclear non-proliferation treaty!

# Conservation golden jubilee

from Vera Rich, London

November 29, 1974 marked the golden jubilee of the All-Russian Society for Nature Conservation, an organisation which has grown over the years to a membership of some 26 million, and which has as its chairman no less a personage than the Deputy Minister of Land Reclamation and Water Economy of the Russian SFSR, N. G. Ovsyannikov. Accordingly, in addition to the official notice of the anniversary, which reported such diverse activities as reafforestation, the protection of beavers, the study of the ecological effects of damming rivers, and the propagation of the correct Leninist attitudes to nature, Pravda has also carried a number of other news items slanted towards conservation interests.

Thus, on November 20, the "temporary rules" for the conservation of Lake Baikal were announced. These rules, confirmed by the Ministry of Land Reclamation and Water Economy after a long and careful study are aimed primarily at preserving the water resources of the lake. In addition to the purification measures already introduced for industrial plant (especially paper and timber mills) on the tributary rivers, the new rules envisage the maintenance of the rivers themselves. All submerged timber is to be removed from the river beds, and the rafting of timber down these rivers is to be stopped entirely. The transportation of timber by means of "water-stable floats" is to be extended. All waters of the Baikal basin and of the lake itself are to be protected from physicochemical and biological pollution of all kinds—and, by means of careful organisation and control of holiday centres, sanatoria and rest-homes, from tourist pollution as well. And, in accordance with the Siberian proverb "While there's forest, there's Baikal", all forestry operations in the area will be carefully monitored to obviate erosion and drying out of the soil, with, in particular, a total prohibition on all tree-felling on slopes with a gradient exceeding 15°.

Again on the subject of forestry resources, a report from Kiev (Pravda, November 21, 1974) notes that in the rice-growing areas in the south of the Ukrainian SSR more than 250,000 tonnes of rice straw go to waste each year. In the very same region, there are two paper and cellulose combines which every year consume up to 300,000 cubic metres of timber, brought from the Arkhangel'sk region on the White Sea. If the rice straw, already on the spot, could be used instead of timber, not only would it conserve several thousand hectares of forestland per year, but would also save the cost and logistics of shipping the timber from the extreme north to the extreme south of the USSR.

"conservation" of human The ecology from natural disasters is also well represented: on November 24, a report on measures against erosion by wind and water in the Caucausus, and Transcaucasia, Kazakhstan, the Urals and Eastern Siberia; on November 27, a report from a hydrotechnical research expedition to the Amu-Dar'ya, the "most capricious" of Soviet rivers, where there is a unique problem of bank erosion, locally known as the Deigish, which can lead to extensive flooding, with destruction of hydrotechnical installations, fields and plantations.

And from Vladivostok, in the interests both of conservation and ecology, an interview with Vladimir G. Osipov, Head of the Sector of Oceanic Pelagic Fish of the Pacific Scientific Research Institute of Fisheries and Oceanography, explains the current interest of his Institute in sharks. Not only are they of interest to the ocean ecologist, standing as they do at the apex of the "food pyramid", and to the palaeoichthyologist-they also represent for mankind "a considerable reserve of protein". Shark's liver is rich in vitamins, and the medical industry has been interested for a long time.

Unfortunately, there remains the hazard to life and limb of those deputed to study and catch sharks. Although shark-repellent substances, electrified barriers, or, "most promising", special nets, can be used to protect bathing beaches, it is clearly impossible to study sharks at long range, and "scientists have recorded a large number of tragedies" while working in this field. Like many ecological and conservation problems, shark harvesting seems a matter of theoretical promise but great practical difficulty.

### Irrationalism and science

SIR,—It is no longer surprising to find scientists consulting the stars or the I Ching to help make decisions, but it is nonetheless depressing. It is a sign of the times—a pandemic disillusionment with political and social institutions. with the past, present and even the future. In its wake, rationalism hides defensively in a few remaining outposts, while mysticism strides about in its various forms, pointing accusing fingers at the anti-human, anti-God, anti-fun, anti-truth, anti-soul, anti-life of science and rationality. Like all trends, irrationalism is not new, but the speed at which it has come upon us this time around and its proportions are a little frightening.

Uri Geller is a case in point. Ten years ago he would have been a charismatic illusionist; today he is a cult figure, believed by many to have various super-human powers normally reserved for Gods and comic-strip heroes. Scientists join him on television programmes and assure us that his feats cannot be explained by present-day science, neglecting the possibility that they may be best understood in the context of present-day magic. That television, radio and newspaper science journalists should join, or even lead the parade of the occult is perhaps not surprising, but that a prestigious scientific journal like Nature should be a credulous participant is a disquieting indication of how far irrationalism has invaded our profession. By acclaiming Geller an important "challenge to scientists" (Nature, 246, 321; 1973) and by publishing an inadequately controlled study on Geller's performance at the Stanford Research Institute (Nature, 252, 559; 1974), Nature has added its prestige to irrationalism and given it a coveted stamp of scientific approval. Rather than making exceptions and lowering standards in order to publish papers of this kind, surely scientists, and the journals that represent them. have a responsibility to themselves, to science and to society to defend the rational approach against the present wave of obscurantism and anti-reason. Although this will raise cries of "scientific elitism", it is simply recognising the definition of science, and approach does not demand the disclaiming of unusual phenomena as impossible, but rather an objective assessment of the probabilities in explaining them, and excluding all natural explanations before turning to supernatural ones. To do otherwise is irrational. A rational perspective on Uri Geller was provided by the *New Scientist* (October 17, 1974).

No matter what the explanations for Geller's various feats turn out to be, he has served to point up two wellknown, but often forgotten facts that deserve publicity and further study. People are remarkably inaccurate observers and reporters of events, even when their professions, such as science or journalism, rely heavily on objective reporting. Suggestion can have powerful effects on the thoughts, sensations and behaviour of most people, which can be useful (as in acupuncture anaesthesia), but which also can be dangerous. It is sobering to think what might happen if anyone believed to have Geller-like powers decided to prognosticate on political or economic issues.

### Pacem in maribus

SIR,-Wendy Barnaby's otherwise fair account of the Pacem in Maribus Convocation (Nature, October 11) gives the impression that I said the "nonconventional" living resources of the ocean-such as squids, krill, lanternfishes—are found mainly in the area beyond the proposed Exclusive Economic Zone. That is not so. The large potential food resources are found both far offshore and rather near coasts. Their geographical distribution is not well known, but the occurrences of high densities are related to zones of high primary productivity. Uncertainty as to jurisdiction over these resources derives less from ignorance of the distributions, than from uncertainty as to the extent of the coastal regime yet to be negotiated. There are many areas of controversy regarding the zonal concept and estimates of the proportion of the total ocean surface which would be under some form of coastal state jurisdiction range from 30 to 90%.

The "unconventional" resource nearest to commercial exploitation is the krill, much of which occurs within 200 miles of the Antarctic continental coastline. With the present Antarctic Treaty in force there would presumably be no EEZ claimed there, but some Parties to the Treaty are considering possible revisions to it to facilitate resource exploitation (*Science*, 184:776–780; 1974). Of the 12 Parties only two are "developing" states. Seven of the remaining ten are affluent northern hemisphere nations, and three of them have active programmes of research and development on krill.

In future either much of the kill resources will be in the waters of the "international zone" or "high seas" or in the coastal zones of a few countries, including perhaps those which successfully lay claim to the Antarctic resources. Similar arguments can be made for other unconventional resources elsewhere. It may be unwise for the developing countries to assume that the potential living resources of the ocean will lie, as do those resources which are now exploited near to their biological limits, mainly within the jurisdictions of coastal states under an EEZ regime. Further, to which particular types of resources (apart from minerals) such iurisdictions will apply, and under what restraints, remains to be determined, with many difficult questions as yet unresolved.

Royal University of Malta, Msida, Malta

### Beware the ghost writer

Sir,—One may sympathise with Dr Cater (Nature, November 29) who has had his work attributed to Dr Carter but what of the attribution of work to authors who do not exist?

In the journal Cancer (29, 1398; 1972) appears a paper by T. Ghose and S. P. Nigam but unfortunately one of the qualifications following Professor Ghose's name is given as M.R.C.PATH and is printed in the same fount as the authors' names.

This has confused several writers quoting this paper who have referred to it as being by Ghose, Path, and Nigam.

The phantom Dr Path has unfortunately been given bibliographical clothes by the cancer abstracting journal Excerpta Medica (Cancer Section) (23; 1973) who give him an entry in their author index.

### A new stable particle: is charm appearing?

INTENSE interest has been aroused by the observation of a new particle with a mass of 3.1 GeV/ $c^2$ . Claims from Brookhaven, New York, where it is called the J meson, and from Stanford, California, where they call it the  $\psi$ , agree so far on its major physical properties. The Massachusetts Institute of Technology group led by Sam Ting has seen a very sharp peak in the mass spectrum of e<sup>+</sup>e<sup>-</sup> pairs, produced when a beryllium target is exposed to the 29 GeV/c proton beam from the Brookhaven Alternating Gradient Synchrotron. The peak is only about 5 MeV/ $c^2$ wide, which is consistent with the resolution of the apparatus, and its production probability is about 10<sup>-7</sup> times the probability for producing strongly interacting particles (hadrons). A Stanford-Berkeley group led by B. Richter used the Stanford electron-positron storage rings 'SPEAR' to produce the new particle directly by e<sup>+</sup>e<sup>-</sup> annihilation. They claim that its width is less than 1.3 MeV, and that it decays to hadrons, to e<sup>+</sup>e<sup>-</sup> and probably to pairs of muons. In contrast to the low relative probability for producing the particle with protons, the electron-positron interaction probability is enhanced by a large factor as a consequence of  $\psi$  (or J) production.

It is clear from the way that the particle is produced that it does not couple strongly to the normal hadrons—the proton and neutron, the hyperons, the pion and kaon, and so on. If it did, then its production rate at Brookhaven should have been much greater. The relatively large production rate at Stanford implies that the  $\psi$  (or J) couples to e<sup>+</sup>e<sup>-</sup> by a simple (lowest order, single photon) electromagnetic process. Weak interactions, as understood at the moment, could not account very easily for the Stanford results.

A particle without strong decays is usually regarded as 'stable', and a width of less than 1.3 MeV/ $c^2$  implies a lifetime of more than  $10^{-21}$  seconds—a long time on the strong interaction scale. If the  $\psi$  (or J) carries only known quantum numbers then it is very hard to see why it should be stable. With 3 GeV of decay energy available it is possible to imagine hadron final states with almost any combination of quantum numbers. As long as such final states can exist, then we would expect strong decays of the  $\psi$ . Electromagnetic decays do not conserve as many quantum numbers as strong decays do. That is why the well established eta meson can decay electromagnetically into three pions, for instance, even though the conservation laws forbid a strong transition from eta to three pions.

Three of the possible explanations for the  $\psi$  deserve mention. The obvious first hypothesis is that it carries a new quantum number which is conserved by strong interactions but is not conserved by electromagnetic processes. This cannot be ruled out, but it is an uneconomical theory since it requires a totally new quantum number to be invented specially to explain this one finding. A second hypothesis is that the  $\psi$  is the intermediate boson which carries the weak neutral current (the intermediate vector boson is a heavy particle, probably as heavy as 40 proton masses, which carries the weak interaction; see Nature, 250, 186; 1974, for the present status of experiments on weak neutral currents). But if the boson mass is only

3 GeV/ $c^2$  we would expect very large differences between the properties of the neutral currents as observed in the CERN Gargamelle experiments with 5 GeV neutrinos and in the Fermi Laboratory experiments with 100 GeV neutrinos. No significant differences have been seen. The third and most elegant hypothesis also incorporates a new quantum number, but one which has already been suggested to explain the absence of strange particle production in neutral-current processes. The  $\psi$  may be inhibited from strong decay because of 'charm'; not because the  $\psi$  itself is a charmed particle, but because it is made of a charmed quark and a charmed antiquark.

Another well established meson, called the phi, also has electromagnetic decays to e+e-. It is not quite a stable particle—it decays by the strong interaction to a kaon plus an antikaon-but it chooses not to decay by the far more accessible channel to three pions. The omega meson, which has all the same normal quantum numbers as the phi, and is lighter than the phi, decays very rapidly to three pions. The absence of a phi to three pion decay has been explained very convincingly by saying that the phi is made from a strange quark and a strange antiquark. In a decay process the strong interaction apparently preserves the quarks that were contained in the decaying particle. The lightest particles which contain strange quarks are the kaons, so the phi either decays to a kaon-antikaon pair, or it decays electromagnetically. If the kaons just happened to be about 10% heavier than they are, then the phi would not be able to decay into them—its mass is 1.018  $GeV/c^2$  and a kaon has a mass of about 0.49 GeV/ $c^2$ .

Perhaps the  $\psi$  is a similar object to the phi. Charmed mesons may exist, like the strange mesons we call kaons, but if the lightest of them is more than half the mass of the  $\psi$  then the  $\psi$  will not be able to decay into a pair of them through the strong interaction.

D. J. MILLER

# Misunderstandings over C<sub>4</sub> carbon fixation

Ecologists concerned with energy flow in ecosystems, and particularly those interested in primary energy fixation, await a clarification of the status, both in energetic and ecological terms, of the recently described C4 pathway of carbon fixation found in certain angiospermous plants. At present the literature presents a rather confused picture. Statements now proliferate which give the impression that there are "two major photosynthetic pathways of carbon assimilation in higher plants" (quoted from Osmond, Aust. J. Bot., 22, 39; 1974). Although such authors, and perhaps the initiates among their readership, may have a clear idea of what this means, to those unfamiliar with the biochemistry of these photosynthetic processes (which probably includes the majority of ecologists) the implication is that the so-called C3 and C4 plants have distinct and dissimilar methods by which carbon is assimilated into the plant tissue. In fact this is not quite true. Although C4 plants possess a novel system for carbon concentration in

which carbon dioxide initially reacts with phosphoenol pyruvate to form oxaloacetate (a four-carbon acid), a second fixation process is necessary prior to the assimilation of the carbon into plant tissues and is achieved by a release of CO<sub>2</sub> from four-carbon acids within the bundle sheath cells, where it is refixed in the chloroplasts by the conventional C<sub>3</sub> mechanism. This involves ribulose diphosphate (five-carbon) and the production of three-carbon molecules (Hatch, in *Photosynthesis and Photorespiration*, edit. by Hatch, Osmond and Slack, Wiley, New York; 1971; and Black, A. Rev. Plant Physiol., 24, 253; 1973). A major significance of the C<sub>4</sub> process is its capacity for operating at very low ambient CO<sub>2</sub> concentrations, when it serves to concentrate CO<sub>2</sub> in the mesophyll cells before passing it on to the bundle sheath cells.

The confinement of the Calvin cycle to the chloroplasts of the bundle sheath cells is by no means proven. Evidence for this is mainly negative in that ribulose diphosphate carboxylase activity has not yet been demonstrated in the chloroplasts of the mesophyll cells, whereas posphoenol pyruvate carboxylase has been shown to be active in the mesophyll cytoplasm. The precise location of the Calvin cycle is still in dispute and some people are inclined to believe that it may occur in the mesophyll (see Coombes, Commentaries in Plant Science, 1, 1; 1973, in Current Advances in Plant Science).

Evidently the initial stage of the  $C_4$  system of carbon concentration is not an alternative to the Calvin cycle  $(C_3)$  system, but is an additional mechanism which can be advantageous in certain environmental circumstances. In many respects it is comparable to the crassulacean acid metabolism of certain succulents. (Laetsch, Am. J. Bot., 55, 875; 1968; also see Nature, 251, 380; 1974).

Another area of misunderstanding is the higher photosynthetic rate and, in some cases, higher primary production rate associated with the C<sub>4</sub> mechanism (Zelitch, Photosynthesis, Photorespiration and Plant Productivity, Academic Press, London and New York; 1971). Many C4 species, such as maize and sugar cane, are among the most productive in the world, and this has led to the assumption that the adaptive significance of the C4 mechanism is one of enhanced productivity. Gifford (Aust. J. Plant Physiol., 1, 107; 1974) has recently examined this concept by considering the relative advantages of the C, system from the molecular to crop growth rate levels of organisation. At the level of initial CO2 reaction, the C4 mechanism may have a 60-70fold advantage (but this is questionable in the light of Bahr and Jensen's work: Plant Physiol., 53, 39; 1974) over the C<sub>3</sub> system, due mainly to the much lower CO<sub>2</sub> concentrations at which it is able to operate. Consideration of leaf mesophyll in vivo shows that this advantage may have fallen to about five-fold at the tissue level due in part, perhaps, to the necessity for refixation in C4 plants.

A comparison of daytime net photosynthesis of  $C_3$  (for example ryegrass) and  $C_4$  (for example maize) crops with similar leaf area indices and under the same growth conditions shows that the  $C_4$  species may have a 1.5-fold advantage at high light intensities, but this declines with lower light availability. If crop growth rates are measured rather than gas exchange under idealised conditions then one finds considerable variation among both  $C_3$  and  $C_4$  species but there is no evidence for consistently higher growth rates among  $C_4$  plants. Gifford concludes that some of the very high forage yields reported from some tropical  $C_4$  grasses, such as *Pennisetum*, may be related to the greater length of the tropical growing season rather than the higher short-term production efficiency of these species.

Evidently there has been some oversimplification regarding the potential advantages of the C<sub>4</sub> sytem; high efficiency at the metabolic level is not necessarily maintained up to the level of plant growth rate. A more likely adaptive significance of the C<sub>4</sub> mechanism of carbon concentration

is the maintenance of growth in water-deficient conditions when open stomata and conventional gaseous exchange may result in water stress. In this context Laetsch (A. Rev. Plant Physiol., 25, 27; 1974) has pointed out that the C4 mechanism is commonest in plants subjected to intermittent aridity whereas the somewhat related process, crassulacean acid metabolism, is associated mainly with plants experiencing permanently dry conditions. As far as productivity is concerned the ecologist and crop physiologist must evidently apply caution before extrapolating from biochemical data.

Peter D. Moore

# **Inertial frames** in relativity

The results of Bishop and Landsberg (page 459) have clarified the rather tangled skein of exposition of relativity theory. They have relevance not only for discussions of the principle of equivalence, which is their concern, but also for the exposition of special relativity which Dingle has attacked on so many occasions. Dingle's attacks have shown the exposition of special relativity to be inadequate, though it is doubtful whether he has shown any deficiencies in the theory.

The key to the whole matter lies in the notion of an inertial frame. Such a frame of reference for space and time measurement occurs both in Newtonian mechanics and in special relativity, and it is assumed in most treatments that the occurrence is the same in each case. Such a view underlies Einstein's heuristic argument by which he managed, as long ago as 1911, to derive from the Doppler shift the gravitational red shift of spectral lines. The essential step here is to transform to a freely falling frame of reference so that the acceleration due to gravity is abolished, by the principle of equivalence, of bodies at a point having the same acceleration. The acceleration in the original frame produces a velocity in the new one, and consequently the Doppler shift. The conclusion is that clocks which were originally synchronised are slower deep in a gravitational field so that the geometry of space-time is modified. Though this argument is only heuristic, it was important for suggesting the principles of general relativity to Einstein, but, as Bishop and Landsberg point out, it is obvious nonsense, since it is entirely carried out in Newtonian physics and therefore a transformation of time is evidently in contradiction to the absolute time concept.

The difficulty lies in the fact that both frames of reference cannot be inertial. Bishop and Landsberg claim to have a theory that gives time stretching in Newtonian mechanics, and gives the Einstein result to the first order in special relativity. Physically, this is not inconsistent with Price's result (Am. J. Phys., 42, 336) earlier this year with the Einstein formula holding exactly in special relativity. The discrepancy arises only from slightly different definitions of acceleration.

The letter from Bishop and Landsberg, however, leaves unconsidered just what is the intrinsic difference between the two theories, and this seems to lie in the different concepts of inertial frames. In special relativity, such a frame is one in which Newton's laws and Maxwell's equations have their usual form, and it is then a text-book exercise to show that any two such frames are connected by the Lorentz transformation, and that the frames are in uniform relative motion. Essential for this derivation is that we have an inertial frame to start with, so in special relativity there is a six-fold infinity of preferred reference frames. The situation in Newtonian mechanics is completely different: the inertial frame is defined very simply by the form of Newton's laws. Then every frame in uniform

relative motion is also inertial and the transformation between them is then a Newtonian approximation to a Lorentz transformation. But there is no preferred set of frames in the absolute sense of special relativity to start with, because, once gravitational fields are allowed, there is no precise set of forces and any frame of reference can be considered inertial so long as we are prepared to introduce sufficiently strange gravitational fields. The only sense in which the six-fold infinity of frames can be said to be preferred is that of convenience.

The basis of Dingle's long-standing arguments with the relativists seems to be his insistence on the arbitrary nature of inertial frames. Neither his antagonists nor he himself have noticed that this arbitrariness is explicitly denied. The current discussion makes all this a little clearer.

C. W. KILMISTER

# Element synthesis and isotope anomalies in the early Solar System

from Grenville Turner

THE chemical elements which make up the Solar System were synthesised by various nuclear processes which occur at different stages in the life cycle of stars. Much of the experimental evidence which verifies in detail the operation of these processes is to be found in elemental and isotopic abundances within the Earth, meteorites and recently, the Moon. Many types of process are known to occur and there are different stellar environments appropriate to each; yet significantly, isotopic abundances are, with very few exceptions, within error uniform throughout those parts of the Solar System so far sampled. This observation implies that the material which came together to form the Solar System was at a very early stage homogenised to a very high degree.

Most of the exceptions to this rule (referred to as isotope anomalies) can be understood in terms of the radio-active decay of some long lived precursor isotope and provide the means of determining such things as the age of the Solar System and the duration of some of the element-building processes. Other exceptions in meteorites and lunar samples can be understood in terms of currently operating nuclear processes induced by cosmic rays. These processes are well understood.

Recently two isotope anomalies have been discovered in the very primitive Allende meteorite. Neither anomaly is currently understood but they may result from nuclear processes operating immediately prior to or during Solar System formation. The first of these anomalies to be found (Clayton et al., Science, 182, 485; 1973) occurs in oxygen in A1-rich inclusions present in Allende. Correlated variations  $(^{18}O/^{16}O)$  and  $(^{17}O/^{16}O)$  ratios can be most easily understood in terms of the presence of variable amounts of the single isotope 16O. Whether this is the correct interpretation or not it seems difficult to escape the conclusion that one is seeing in Allende the results of the incomplete mixing of the products of nuclear synthesis.

The second recent observation concerns the isotope <sup>26</sup>Mg. <sup>26</sup>Mg is the daughter product of <sup>26</sup>Al, an isotope which has aroused much speculation as a possible heat source during the early history of the Solar System. The need for a heat source capable of heating planetary objects on a rapid time scale arises from a number of arguments. Chemical arguments based on the presence in meteorites and the Earth of volatile elements suggest that solid material originally condensed at relatively low temperatures to form the Solar System. In contrast there is much evidence that a number of processes requiring high temperatures occurred within the first hundred million years of Solar System history; for example, the melting of iron to form iron meteorites, and magmatic differentiation of rocks on the Moon and in certain classes of stone meteorites. The heat source responsible is currently a matter for speculation, 26Al being only one of a number of possibilities.

Stimulated partly by the search for a heat source several attempts have been made to search for the 26Mg anomalies which would result from in situ decay of 26Al. Two factors make the search a difficult one. First of all <sup>26</sup>Al has a geologically short half life, 7.4×105 yr, and so the search must be confined to the most primitive of meteorites to have any chance of succeeding. Second, Mg is itself an abundant element and the anticipated anomalies would be undetectable in all minerals but those most poor in Mg and rich in Al. The search for 26Mg anomalies has had a chequered career and ar early claim to have detected them (Clark et al., J. geophys. Res., 75, 448; 1970) was later shown by an exhaustive series of measurements to have been incorrect (Schramm et al., Earth. planet. Sci. Lett., 10, 44; 1970).

A recent issue of *Nature* contains one of the latest additions to the saga. Gray and Compston (*Nature*, **251**, 495; 1974) have continued the search in the Al-rich inclusions of Allende, following the observation of the <sup>16</sup>O anomalies and encouraged by Sr isotope data

which indicate that these inclusions are the most primitive material known to man (Gray et al., Icarus, 20, 213; 1973). After a series of measurements, on the meteorite and three inclusions, they are able to report a small but significant anomaly for one of the inclusions which would correspond to an 0.4% excess of 26Mg. The (Al/Mg) ratios of the other two inclusions are less favourable and an anomaly, if present at an equivalent level, would be barely detectable. Gray and Compston conclude that if the anomaly is the result of in situ 26Al decay then the implied initial concentration of 26Al would represent a significant early Solar System heat source.

A second group of research workers have been searching for Mg anomalies in Allende and their results have also been published recently (Lee and Papanastassiou, Geophys. Res. Lett., 1, 227; 1974). This work, coming from the laboratory which painstakingly laid to rest the early claims of <sup>28</sup>Mg anomalies, indicates that, in Allende at least, anomalies are present. A most significant finding is however that in one of the samples the anomaly is negative—which appears to rule out in situ decay of <sup>28</sup>Al as the cause of the anomalies.

Lee and Papanastassiou have performed 39 analyses on 21 distinct samples from Allende and found anomalies in nine of the samples. The anomalies are found in the Al-rich inclusions and expressed in terms of the (26Mg/ <sup>24</sup>Mg) ratio range from -0.17% to +0.30% with typical uncertainties of around 0.02%. The shifts are much smaller than those found in oxygen, which range up to 5%. Moreover there seems to be no direct correlation with the oxygen anomalies in that the samples with large oxygen anomalies show no magnesium anomaly. There is also no correlation with (Al/Mg) ratio and this in addition to the negative <sup>26</sup>Mg anomaly referred to above argues against in situ decay of 26Al. The authors suggest a number of possible nucleosynthetic processes which could lead to enrichment or depletion of various Mg isotopes but argue that the absence of a correlation with the oxygen anomalies hinders the identification of a single process as the cause.

In summary there is now a growing body of evidence for the presence in meteorites of the products of nucleosynthesis which have not been thoroughly mixed. To the O and Mg anomalies should be added two as yet unexplained anomalies in the inert gases Xe and Ne (Black. Geochim. cosmochim. Acta., 36, 377; 1972). The explanation of these effects is a challenge which, if met, will add greatly to our understanding both of the processes of nucleosynthesis and of the early evolution of the Solar System.

### A promotory effect of inflammation on tumour initiation

from A. J. S. Davies

To its devotees tumour immunology is an absorbing pastime. To them the facts that T lymphocytes and B lymphocytes and macrophages can all in their different ways be cytotoxic, at least in vitro, are mutually compatible. The existence of anti-tumour antibodies that can be thought of as cytotoxic or enhancing or blocking is regarded with joy. The possibility that antibody-tumour-antigen complexes or tumour antigen alone can reduce the aggressive anti-tumour effects of some of the various kinds of hostile lymphocytes becomes part of the grand design. On this euphoric wave of complexity the tumour immunologists are carried as they invent even more and bizarre ways of immunotherapy. Their methodology comes increasingly to resemble some of the early attempts to control bacterial diseases by methods that retrospectively were seen to be nonspecific and unreliable.

This is not to say that the tumour immunologists are wrong all the way along the line. There may really be an immunological surveillance mechanism which eradicates most tumours before they become a nuisance. When this mechanism has failed there may be tumour-specific immune responses in all instances which can be manipulated for the benefit of the patient. But the greater the economic pressure on scientists engaged in this biomedical research the more positive will be the assertions, not necessarily justified, that a particular theory is correct. A recent paper in the British Journal of Cancer by van den Brenk et al. (30, 246-260; 1974) blows a breath of fresh air into the arena.

Van den Brenk and his colleagues have worked on the effects of various inflammatory and anti-inflammatory agents on the survival and growth of clones of injected foreign tumour cells in rats. For example, they found that injection of cellulose sulphate ten minutes before intravenous injection of the Walker-256 adenocarcinoma caused substantial increases in the number of tumour cells starting to grow in the lungs and as a consequence a marked increase in tumour weight. This was even true in immune mice though immunisation always had some protective effect. From other experiments cellulose sulphate is known to be a powerful inducer of inflammation by some mechanism that is not altogether clear. Cellulose sulphate is also an anticoagulant and can be fibrinolytic.

In spite of the complexity of its effects the authors of the experiments feel and present additional evidence that the inflammatory properties of cellulose sulphate are those responsible for its augmentary effect on tumour seeding and thus tumour growth. In other experiments injection of a lung homogenate is shown to have a similar augmentary effect by means which are thought to be pharmacologically the same as those involved in the effect of cellulose sulphate. Direct effects of either lung homogenate or cellulose sulphate on tumour growth seem to be ruled out in control experiments. Experiments were performed in which tumour and inflammatory agents were injected in the rats' forepaws. Again cellulose sulphate caused some enhancement of tumour growth.

It would be nice to see these experiments repeated with syngeneic tumour implants. But there are many interesting corollaries of the present findings which should be read about in the original. One of the specific points made by the authors is worth underlining here. They say that a situation can arise wherein the survival and growth of tumour cells are inhibited by immunity but stimulated by inflammation resulting from the destruction of participating host and tumour cells. This provides food for thought for tumour immunotherapist and radiotherapist alike especially as Stjernswärd now claims to have evidence (Lancet, ii, 1285; 1974) for decreased survival related to postoperative radiation in early operable breast cancer. Van den Brenk and his associates have shown moreover that injection of an antiinflammatory steroid could reduce the augmentary effect of cellulose sulphate on the seeding of tumour cells. The old fashioned view that tumours should be thought of in the light of the naturenurture paradigm is perhaps worth reconsideration particularly if damaged cells can nurture (albeit indirectly) their intact tissue-mates.

# Superfluid <sup>3</sup>He at zero pressure

from P. V. E. McClintock

LIQUID <sup>3</sup>He has been cooled to temperatures below 0.7 mK in a nuclear demagnetisation cryostat and, under its own saturated vapour pressure, it was found to undergo a superfluid transition at 0.93 mK. The experiment, which was performed at the Helsinki University of Technology by Ahonen, Haikala, Krusius and Lounasmaa, is described in a recent issue of *Physical Review Letters* (33, 628; 1974).

Since the discovery in 1972 that

liquid <sup>3</sup>He under a pressure of 24 atmospheres undergoes two separate transitions at temperatures of about 2.7 and 2.2 K, intensive efforts, both theoretical and experimental, have been made towards gaining an understanding of the two new phases of the liquid. The experiments have, until now, all employed one of two cooling methods: either compressional solidification of 3He, known as Pomeranchuk cooling, which restricts experiments to the solidification pressure of 34 atmospheres; or adiabatic demagnetisation of cerium magnesium nitrate (CMN), which can be carried out at any pressure. Using these techniques, a remarkable amount of information concerning the nature of the new phases has been gained from a variety of experiments including, in particular, nuclear magnetic resonance (NMR) measurements. It has been shown that both the higher temperature so-called A phase and the lower temperature B phase exhibit superfluid properties; and that, as the pressure is reduced with zero applied magnetic field, the higher temperature transition moves to lower temperatures, while the lower temperature one moves to higher temperatures, with the two transitions meeting in a tricritical point at about 20 atmospheres. Below 20 atmospheres only the B phase is stable, and the transition was found to move to lower temperatures with falling pressure. It was not feasible by demagnetising CMN to follow the transition below about 15 atmospheres and 2.2 mK, so that is was impossible to say whether or not the transition would ever reach zero pressure: it seemed quite credible that 3He might not be superfluid under its saturated vapour pressure, but would always require the application of external pressure to undergo the superfluid transition.

The ultimate low temperature attainable with CMN is related to the spontaneous ordering of the electron spins on the cerium ions as a result of their mutual magnetic interaction. To reach temperatures significantly below 2 mK an assembly whose magnetic elements interact less strongly is therefore required, and the Helsinki group chose to demagnetise copper nuclei in order to achieve their cooling effect. In essence, the technique is simple. When a large magnetic field is applied at a starting temperature of less than 20 mK, the copper nuclei tend to align themselves, and heat is liberated and is removed by means of a dilution refrigerator. The thermal link to the refrigerator is then broken and the magnetic field very slowly reduced to zero, resulting in cooling as the nuclei disorientate themselves again.

In practice, great care has to be taken in minimising heating due to the eddy currents which are liable to be induced in the copper as the field is run down; and possible heat leaks, whether through conduction, radiation or mechanical vibration, have to be forseen and eliminated by suitable design as far as is humanly possible. To avoid the eddy current heating the Helsinki group used a very large bundle of separate high purity 0.1 mm diameter copper wires, insulated from each other along most of their length. The top ends of the wires, well away from the demagnetising field, were all welded together into a piece of copper, which in turn was welded to the copper chamber which held the 3He.

Earlier calculations had suggested that extreme difficulties might be encountered in achieving good thermal contact between the copper and the liquid 3He, with a thermal boundary resistance varying as T<sup>-3</sup> and the probability that nuclear demagnetisation could not be used to cool 3He below 2 mK. For this reason the cell was designed in such a way as to present as large as possible a surface area of copper to the liquid: most of the volume was filled with a sponge of sintered copper powder, so that the 6 cm3 of 3He was in contact with about 30 m<sup>2</sup> of copper surface. In fact, the authors found that the problem was much less severe than had been anticipated, probably owing to thermal transfer through an unforseen direct interaction between the nuclear magnetic moments of the 3He atoms and the electronic magnetic moments of manganese impurities in the copper, resulting in a boundary resistance which varied only as  $T^{-1}$ .

Demagnetising from a starting temperature of 17 mK over a period of 3.5 h, a final temperature for the <sup>3</sup>He of just below 0.7 mK was achieved. A measure of the quality of the experimental design is given by the fact that it then took 20 h to warm up to 1.0 mK.

By performing experiments at various pressures, and detecting the phase transitions by means of characteristic changes in the NMR signals, the authors traced out the phase diagram, and were able to follow the superfluid transition right down to zero applied pressure at a corresponding temperature of 0.93 mK. This means that, at least in principle, it should now be possible to do experiments involving the free surface of the liquid.

This impressive cryogenic achievement by the Helsinki group means that, for the moment, they enjoy a clear lead over all competitors. It will be interesting to see how they will exploit their advantage, and what illuminating experiments they will perform to eluci-

date the nature of the new superfluids, particularly that of the relatively unknown B phase, now that they have developed the necessary technology.

# Receptors for neurotransmitters

from Key Dismukes

THE mechanisms by which a neurotransmitter, interacting with postsynaptic receptors, induces characteristic neural response remain shrouded in mystery. In recent years much has been learned about hormone receptors in various tissues by probing their interactions with radiolabelled ligands, compounds known to be bound by the receptor with great affinity and selectivity. Synaptic receptors in the brain present a far more difficult problem because of the heterogeneity of neurones, relatively low concentrations of receptors, and thir occlusion within the synapse. Nevertheless, there is great impetus to study these receptors, both to elucidate basic neural mechanisms and because many important psychoactive drugs operate through these sites.

The crucial step in biochemically. characterising a receptor is to demonstrate that a ligand (often an analogue of the endogenous neurotransmitter) incubated with tissue homogenate selectively binds the receptor in question. Early reports of isolation of acetylcholine receptors from brain have been discounted because the binding was apparently nonspecific, failing to parallel known pharmacological properties of the receptor. Extremely low concentrations of ligand must be used because the limited number of true receptors is soon completely occupied, whereas nonspecific tissue binding increases indefinitely with ligand concentration.

Pharmacologists have described two kinds of acetylcholine receptor: nicotinic and muscarinic. The nicotinic receptor of the electric organ of electric eels was the first to be identified biochemically, and has been investigated extensively by several groups. Although the nicotinic receptor in mammalian brain tissue has resisted definitive biochemical demonstration, several groups have successfully studied muscarinic receptor properties in mam-•malian brain and peripheral tissues. As long ago as 1965, Paton and Rang detected binding of radioactive atropine, the classic muscarinic antagonist, to the guinea pig intestine (Proc. R. Soc., B163, 1; 1965). But the low specific radioactivity of the atropine then available precluded extensive biochemical characterisation.

Recently, Yamamura and Snyder

have examined the binding of a potent muscarinic antagonist, 3-quinuclidinyl benzilate (QNB), using techniques developed for studying the opiate receptor (Proc. natn. Acad. Sci. U.S.A., 71, 1725; 1974). Binding of 3H-QNB was found to be almost completely blocked by excess cold QNB, indicating that the interaction was saturable, and thus specific. Muscarinic antagonists and agonists displaced specific 3H-QNB binding, but nicotinic and non-cholinergic agents showed no affinity for ONB binding sites. These experiments indicated a concentration of muscarinic binding sites similar to that of the nicotinic receptor of the electric organ of the electric eel. The electric organ has been presumed to be extremely densely innervated, but apparently is no more so than the brain is with muscarinic receptors—which is notable, considering that only a small portion of the brain's synapses are likely to be muscarinic.

Burgen, Hiley, and Young have found closely similar features of muscarinic cholinergic receptor binding in rat brain by using <sup>3</sup>H-propylbenzilycholine, an antagonist related to nitrogen mustard which binds irreversibly to the receptor (*Br. J. Pharmac.*, **51**, 279; 1974). Similarly, Soudijn, Wijngaarder, and Ariens have had success with an atropine-like agent, dexetimide (*Eur. J. Pharmac.* **24**, 43; 1973)

Rigorous evidence that QNB binds specifically to acetylcholine receptors was obtained by comparing the pharmacological potency of a number of cholinergic agents with their ability to inhibit 3H-QNB binding in guinea pig ileum. Acetylcholine is known to produce contractions of the guinea pig intestine through a muscarinic receptor. For each muscarinic agent a close parallel was found between the concentration necessary to block 3H-QNB binding 50% and the concentration producing half-maximal response of the intestinal strip. Nicotinic agents and non-cholinergic drugs which do not stimulate the ileum did not alter 3H-QNB binding.

The team of Yamamura, Kuhar and Snyder is now using 3H-QNB binding to examine the distribution of muscarinic receptors in brain. Binding was examined after destruction of septal cholinergic tracts to the hippocampus (Brain Res., 78, 320; 1974). Although cholinesterase activity was drastically reduced by this treatment, there was no alteration of 3H-QNB binding, suggesting exclusively post-synaptic localisation of these receptors. A detailed regional map of receptor concentration has been obtained in monkey brain (Brain Res., 66, 541; 1974). Because of its extremely high affinity, 3H-QNB can selectively label the brain's muscarinic

receptors even when administered in vivo. After in vivo labelling of receptors, it was found possible to perfuse the brain to preserve microscopic structural integrity, thus permitting direct visualisation of receptors by autoradiography (Brain Res., 80, 170; 1974)

Using procedures similar to those of the acetylcholine work, Young and Snyder have studied the binding of <sup>3</sup>H-strychnine to synaptic membrane fractions from spinal chord and brain stem (Proc. natn Acad. Sci. U.S.A., 70, 2832; 1973). Strychnine is known to be a potent and specific antagonist of glycine, a major inhibitory neurotransmitter. The binding of strychnine seems to be associated with the synaptic glycine receptor, since the ability of glycine and various other amino acids to inhibit 3H-strychnine binding closely parallels their glycine-like neurophysiological activity. Furthermore, the distribution of <sup>3</sup>H-strychnine binding in the brain closely resembles the distribution of endogenous glycine, neuronal sensitivity to and nerve-ending uptake of glycine.

Interestingly, Young and Snyder find that glycine and strychnine seem to bind to interacting, but separate portions of the receptor (Molec. Pharmac. 10, 790; 1974). Glycine displaces 3H-strychnine in a cooperative manner, and its binding can be blocked by various reagents which do not interfere with the binding of strychnine. The inhibitory postsynaptic potential (IPSP) caused by glycine can be reversed by iontophoretic injection of various anions, apparently on the basis of their ability to traverse the membrane's ionic gate for chloride. A close correlation was discovered between the ability of a series of anions to reverse the IPSP and their displacement of bound 3Hstrychnine. This suggests that the binding of strychnine is closely associated with the chloride conductance gate triggered by the glycine receptor. This discovery may be a valuable tool to elucidate the mechanisms by which receptor activation alters membrane conductance.

One of the most intriguing questions of receptor theory is the difference between agonists and antagonists. Why does one type of agent binding the receptor stimulate the characteristic cellular response and another type, binding equally well, produce no effect? Several theories have been proposed, but pharmacological data are not sufficient to distinguish any one. These biochemical binding techniques, being fervidly developed in several laboratones, allow scrutiny of receptor interactions at a level which may answer this and other basic pharmacological questions.

### Gallium nitride, a valuable semiconductor

from A. G. Holmes-Siedle

Semiconducting compounds of elements in groups III and V of the periodic table, such as gallium arsenide (GaAs) could be called the second generation of useful semiconductors. They are isoelectronic with silicon but generally adopt the zinc-blende rather than the diamond crystal form. This leads to a considerable difference in the band structure and to the manyvalley feature which permits the very useful Gunn oscillations in GaAs. The array of possible defect centres is intrinsically more diverse than that for silicon because either of the two types of atom present can be replaced in the lattice. This has not prevented the development of devices which employ the radiation emanating from the defect centres during electron-hole recombination. (These devices, light-emitting diodes and injection lasers, have greatly improved numerical displays and may vet revolutionise communications.) By mixing the compounds of gallium, aluminium, arsenic and phosphorous, layered junction structures can be made which emit light of wavelengths varying from 0.5  $\mu$ m (2.4 eV, green) to  $0.9 \mu m$  (1.4 eV, infra-red). One member of the series, however, gallium nitride (GaN) is not so easily prepared and does not mix successfully with the other members; this is a pity since it is a material with great potential.

Of all the III-V compounds, GaN has the widest forbidden band gap (about 3.5 eV) and can be induced to luminesce in the blue, violet or ultraviolet regions (the ultraviolet starts at 0.4  $\mu$ m). Also, since the band-edge absorption occurs in the ultraviolet (0.35  $\mu$ m), pure crystals of GaN are colourless and transparent. In spite of the wide band gap, crysals as grown may often have resistivities as low as silicon and also have fairly high carrier mobilities; if it could be made, the intrinsic or "i" material would be of very high resistivity indeed.

Clearly this is an unusual and potentially useful semiconductor although preparative problems have prevented its use in electronic devices up to now. Not only is it difficult to control the impurities which give high electron concentrations (n-type material); it is equally difficult to find and introduce impurities which produce p-type material. Thus, no good method of forming a p-n junction structure (an integral part of the conventional light emitter) has been found. But there are signs that other practical methods may be found to produce a luminescing

film, for example the generation of avalanche currents by pulsed fields (Pankove and Norris, RCA Rev., 33, 377; 1972) and there are now signs that GaN may be nearly ready for use in device technology. It may thus be worth while for physicists and chemists to survey some of the known facts about the physics of GaN, aided by a concise review by F. P. Kesamanly (Soviet Physics, Semiconductors, 8, 147; 1947).

A serious drawback to incorporating GaN into the conventional layered III-V alloy laser structures is that, in contrast to all the other III-V compounds shown in Table 1, which crystallise in the zinc-blende form, GaN has the wurtzite structure. GaN was first synthesised in 1932, well before the discovery of semiconducting properties in the III-V compounds. Growth of large single crystals has, however, always proved difficult. Only recently has it been found possible to grow the desired large-area films by epitaxial growth on sapphire, using the disproportionation of gallium chloride and ammonia. This can yield films up to 240  $\mu$ m thick with an electron density of 2.1017 cm-3 and an electron mobility of  $380 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ at room temperature. It has not generally been possible to grow films of lower electron density. But there are reports that Pankove has produced layered structures in which semi-insulating GaN film (that is, electron density presumably well below 1014 cm<sup>-1</sup>) is overlaid on a strongly n-type film deposited on sapphire. This may give the essential parts of an avalanche electroluminescent diode which can possibly emit light at fairly high power.

While the semiconductor world was awaiting the development of a suitable structure for carrier generation in GaN, investigators were assessing the luminescent transitions by photoexcitation techniques, starting with Grimmeiss and co-workers in 1960 (Z. Naturforsch, 15a, 799). It was encouraging to find several strong luminescence peaks in the ultraviolet, at 3.47 eV (0.36  $\mu$ m), 3.29  $(0.38 \ \mu m)$  and 3.16  $(0.39 \ \mu m)$ . R Dingle and colleagues (J. Appl. Phys., 43, 3797; 1972) proposed that the 3.4 eV band was the result of recombination of excitons bound to neutral donors and neutral acceptors. Grimmeiss

Table 1 Comparison of properties of III-V semiconductors (300 K)

•	GaN	GaP	GaAs	GaSb	)
Band gap	3. <i>5</i>	2.24	1.43	0.67	
Electron mobility	380	110	8,500	400	
D J	InN	InP	InAs	InSb	AlSb
Band gap	<1.9	1.29	0.33	0.16	1.63
Electron mobility	<b>— 4</b> ,	600 3	3,000	78,000	200

instead attributed the 3.4 eV peak to recombination of free excitons. The doping of GaN with impurities either gives rise to new bands or enhances the triplet. Grimmeiss reports that the doping of gallium nitride with lithium, sodium, copper, silver, gold, zinc, cadmium, barium, mercury, tellurium, tin and lead gives rise to photoluminescence bands with maxima at twelve different wavelengths in the violet to yellow range; mercury produces a band with a maximum at 2.1 eV (0.59  $\mu$ m, orange). Doping with beryllium, magnesium, calcium, aluminum, and indium produces no new bands but enhances the ultraviolet emission. Soviet workers have found acceptor levels on doping with zinc, cadmium, and lithium; these levels are located 0.40, 0.69, and 0.95 eV above the top of the valence band.

Gallium nitride has been used in the construction of luminescent MIS (metal-insulator-semiconductor) diodes with a Si<sub>3</sub>N<sub>4</sub> insulator film 0.1 μm thick (Pankove and Norris, loc. cit.). The luminescence spectra of such diodes include a wide band of 2.1 eV energy (0.59  $\mu$ m, orange) and an ultraviolet band at 3.28 eV. Green-emitting MIS diodes based on zinc-doped GaN and magnesium-doped GaN have been made in this way: the latter material emitted in the violet part of the spectrum. The efficiency of these structures was 10<sup>-5</sup>. Diodes emitting yellow light and characterised by an efficiency of 4.10-4 were prepared from n-i structures with the high resistivity regions doped with zinc. This is comparable to the efficiency of gallium phosphide green light emitters. In these n-i structures, the light was produced by a pulsed voltage, of, say, 30 V, applied to a metal electrode over the i layer. The light emitted could, of course, be viewed readily through the sapphire substrate. and segmented displays have been made in this fashion. Moreover, it is understood that these devices have operated for several months without degradation in performance. Kesamanly (loc. cit.) also reports that GaN will alloy with indium nitride and that the band gap is adjustable thereby.

It thus seems that GaN is on the threshold of becoming a new tool in the hands of the semiconductor physicist. It will be more versatile than other III-V compounds both because the diodes will emit light over the whole of the visible range and because GaN is completely transparent in the visible. It will be of great interest to see what benefits this will bring to our technological repertoire and which country (the United States, United Kingdom, Soviet Union, Germany) leads the way in developing new gadgets—say a whitelight laser or solid television displayfrom this advance.

# Dilatancy without fluid flow?

from Peter J. Smith

It should be quite possible to predict earthquakes on a purely phenomenological basis with little, if any, understanding of the physical process involved. All that would be necessary would be to find a premonitory effect which is common to all earthquakes, or at least to a class of earthquakes large enough to give prediction some practical significance. In recent years, for example, it has been observed that, before some shallow events, the seismic wave velocity ratio  $V_P/V_s$  suddenly decreases and then rises again to its normal value just before the shock takes place. This phenomenon may or may not turn out to be a way of predicting shallow earthquakes on a routine basis; but whether it does or not need not depend on any insight into the cause of the velocity changes.

Nevertheless, there is some advantage in having a physical model to explain the observations. For one thing, it tends to inspire confidence; and if there is one thing likely to be required in abundance when it comes to practical prediction, it is confidence. More specifically, an understanding of the mechanisms involved may lead to the discovery of new relationships, and thus bring practical prediction closer. For example, there can be little doubt that the dilatancy model, first proposed by Nur (Bull. Seismol. Soc. Am., 62, 1217; 1972) and subsequently developed and modified by others, has done almost as much as the observations themselves to produce the new wave of optimism in prediction work. By relating the various premonitory effects such as  $V_p/V_s$ changes, resistivity variations and the migration of seismicity to a common mechanism and a common precursor time-earthquake magnitude scale, the dilatancy theory has produced the comfortable feeling that everything is beginning to fit nicely together.

But is the theory correct? Or to put the question in the more limited form that Stuart (Geophys. Res. Lett., 1, 261; 1974) now puts it: are the current dilatancy models involving fluid flow correct? Insofar as there have been no serious objections to the dilatancy-fluid diffusion mechanism, the question may seem superfluous. But as Stuart points out, the theory apparently defies Occam's razor by introducing fluids without a proven need. Moreover, there are good scientific reasons for questioning the occurrence of fluid diffusion, described by Stuart as the "requirements of ubiquitous finite permeability, existence of pore fluid, and ostensibly great distances involved for large

earthquakes".

Stuart's new model has the earthquake occurring within a relatively thin shear zone which has mechanical properties quite different from those of the crustal rocks further away. In the shear zone, the energy applied during deformation is dissipated by creep. In the surrounding crustal rocks, on the other hand, the deformation energy is stored elastically until such time as it is released in an earthquake. Assuming that the two regions are each homogeneous and in welded contact, their stresses at any time will be similar but the strains will differ significantly. To a first approximation the outer rocks will have a linear stress-strain relationship, whereas the shear zone is assumed to have a stress-strain curve possessing a maximum stress.

The crustal rocks in Stuart's model thus have properties comparable to those of the material in conventional dilatancy models; and these rocks are likewise assumed to possess cracks and fractures. The crucial difference is the non-linear behaviour in the thin shear zone. As the stress applied to the combined system increases, dilatancy will occur as the cracks open in the crustal rocks, giving rise to a decrease in  $V_p/V_s$ . But as the stress continues to increase, dilatancy in the crustal rocks will reach a maximum and then decrease as the cracks begin to close up again,  $V_P/V_S$ will correspondingly increase. The earthquake will occur when  $V_p/V_s$  is back to normal, if the energy conditions are favourable. (If the conditions are not so favourable. Stuart's model suggests that rapid creep might occur instead; in other words, the model implies that similar premonitory events herald both earthquakes and accelerated creep.)

It seems, therefore, that the  $V_{\rm P}/V_{\rm s}$  changes observed in the field may be explained quite well without involving fluid; the inflow of fluid (to raise  $V_{\rm P}/V_{\rm s}$ ) in conventional dilatancy models is replaced in Stuart's model by closing cracks. Fluids may indeed be present, but they are not necessary to the argument. Qualitatively, the two models predict similar precursory variations in  $V_{\rm P}/V_{\rm s}$ , resistivity, and so on.

But there is at least one difference which should enable the models to be distinguished. In Stuart's model the dilatancy reaches a maximum and decreases to vanishing point before the earthquake as the cracks close. In the diffusion model the dilatancy goes on increasing up to the earthquake. Moreover, because it is diffusion controlled, the dilatancy in the latter case will only decrease slowly after the shock. In time, therefore, it should be possible to test the validity of the two models by geophysical measurement.

### Retarded cores, black holes and galaxy formation

John Gribbin\*

Recent astronomical observations have given rise to suggestions that black holes may reside at the centres of many or all galaxies. The evidence remains equivocal; and in the meantime there is a theoretical variation on this theme, in which galaxies grow on retarded cores — 'white holes' — which have been present since the initial big bang.

During the past few years the concept of black holes has moved out of the specialist astronomical literature into a broader arena of discussion. This has come about chiefly because of the interest aroused by the discovery of sources of intense X-ray emission which seem, from the periodic variations of systems which are taken to be binary stars, to be too massive to exist as stable stars without producing visible optical radiation. Since no optical counterpart can be detected for these objects, it has been suggested that they have evolved from burnt out massive stars which have collapsed, now that nuclear reactions no longer provide the energy necessary to hold them up, into black holes.

The idea is certainly attractive, and it has the advantage that such a collapsed object would indeed be able to 'drive' the observed X-ray emission, through the conversion of gravitational potential energy into radiation as matter falls into the black hole. It is not yet clear, however, that it is strictly necessary to invoke black holes to explain the X-ray sources observed so far; the evidence is persuasive, but other more or less bizarre ideas (such as differentially rotating white dwarf stars, or models based on triple rather than binary systems, see ref. 1) can also be made to fit the observations.

Whether or not they prove to be the correct explanation of X-ray sources, the excitement aroused by recent work has tended to obscure the fact that black holes are not a recent idea. In fact, such objects have been contemplated by the mathematicians for many years, and whether or not stellar mass black holes exist in star systems in our Galaxy that kind of object could play an important part in the evolution of the Universe, or of individual galaxies. In many ways, the concepts involved in studying the consequences of the existence of such large mass black holes are just as exciting as the possibility that smaller black holes exist in our immediate astronomical neighbourhood; so this may be a good time to examine recent progress from these older ideas.

### Observational evidence

It seems likely that elliptical galaxies contain massive 'black holes'—objects collapsed within their Schwarzschild radii—in their nuclei (see, for example, Wolfe and Burbidge²). The principal evidence in favour of this concept is the 'missing mass' problem; the average mass of a bright elliptical is  $8\times 10^{11}~M_{\odot}$  and the mass-to-light ratio is about 70, implying that the light from these ellipticals can be explained in terms of the emission from stars which make up only some 25% of the mass. There is no similar mass-to-light problem with spirals, but the data are insufficient to rule out the possibility that spirals (including our own Galaxy, see ref. 3), also contain black holes.

But if black holes do exist at the centres of galaxies, it is

something of a problem to account for the evolution of them in terms of gravitational collapse. Wolfe and Burbidge mention in their paper the possibility that such central objects might be related to the 'retarded cores' discussed by Novikov<sup>4</sup> and by Ne'eman<sup>5</sup>, and by others since 1965. A straightforward calculation in the Newtonian approximation shows that the constraints imposed on the nature of elliptical galaxies by assuming that they form on such cores are in complete accord with the limits imposed on the masses of the central black holes from a study of the structure of elliptical galaxies.

### Limits on the size

Following Wolfe and Burbidge<sup>2</sup>, I take the energy generation 'requirement' of an elliptical galaxy to be  $10^{81}$  erg, allowing the galaxy to become a strong radio source. This is equivalent in mass terms to  $10^7 \, M_{\odot}$ , and since there is evidence that recurrent outbursts can occur in radio galaxies, a total of some  $10^9 \, M_{\odot}$  seems to be required to power the observed phenomena. For such a mass, the Schwarzschild radius  $(R_s)$  is about  $10^{-4}$  pc; for a mass of  $10^{11} \, M_{\odot} \, R_s$  is about  $10^{-2}$  pc. There seems little doubt that the energy which drives radio sources must be gravitational in origin, and according to Wolfe and Burbidge "on the basis of conventional theory, it must be argued that ellipticals which have given rise to radio sources contain black holes", because of the requirement that large masses must now be concentrated within regions a few light years across in order to explain the energy production.

From studies of the velocity dispersion in the inner parts of some elliptical galaxies Wolfe and Burbidge are able to set limits on the size of any central black hole. I shall assume that the required mass is not present in the form of many smaller black holes, although this possibility cannot be ruled out by present data. It then turns out that the mass required to explain the observed distributions must in general be less than some  $10^{10} M_{\odot}$ , and that for systems which are relaxed the central mass must be less than  $10^9 M_{\odot}$  (ref. 2).

### Possible size of retarded cores

The concept of retarded cores of expansion arises naturally if we consider time reversal of the present expanding Universe. To an observer A in a region which is less dense than the region inhabited by another observer B there must come a time when observer B disappears behind the event horizon of a black hole as his region of space contracts within the value of  $R_s$  appropriate for the density it has.

\*By considering the time reversal of this situation, it seems reasonable to argue that in an expanding universe which is not of uniform density observers in regions of less than average density will see regions of greater density expanding away from their Schwarzschild radii. Such relatively dense regions would therefore appear as 'white holes', and their expansion would presumably follow essentially the same rules as the

<sup>\*</sup>Nature, London

expansion of the whole Universe. It is postulated<sup>4,5</sup> that the expansion of such cores is delayed in some way, hence their description as 'retarded cores'. Eardley<sup>6</sup> has suggested that because of accretion any white hole existing in the Universe would rapidly be turned into a black hole, because of accretion from its surroundings.

This is more or less what one would expect from commonsense arguments, but the Universe may not be run in a 'commonsense' way. Since the whole concept depends to some extent on tinkering with the boundary conditions of the big bang, it is not unreasonable to argue (P. C. W. Davies, personal communication) that the Universe adjusts itself in some way to counteract the tendency of white holes to extinguish themselves by accretion. That argument is not entirely satisfactory. But the case against white holes is not yet proven, and in what follows the existence of either black or white holes will suffice to 'seed' galaxy formation. Even if an initial white hole or delayed core is converted into a black hole, its mass will still act on outside material in exactly the same way.

It could be argued that there is no evidence that the Universe was ever in a suitable state of inhomogeneity to give rise to such cores; but then, there is no evidence that it was not, and it also seems (see Misner, Thorne and Wheeler?) that an initially random 'mixmaster' type of universe would rapidly evolve into a state very like an Einstein-de Sitter universe with some inhomogeneity. What happens to the region of the universe near to such a retarded core as the universe expands? Locally, gas will be restrained from the general expansion by the gravity of the core, and if stars form in the resulting gas cloud we may expect a galaxy to be produced.

There seems no need to look further than the Newtonian analogy of the Einstein-de Sitter universe for a first model to describe the behaviour of the cloud around the retarded core. For a homogeneous cloud of mass M we have

$$r^2 = 2GM/r$$

Ideally, the calculation should be carried through with some mass—the retarded core—kept within some confine (presumably its Schwarzschild radius) at the centre of the cloud from the start of expansion. But that involves a full mathematical treatment, and a simpler calculation in the Newtonian approximation may suffice to indicate the broad outlines of what is going on. The trick is to allow a mass  $\mu$  to appear at the origin of r at a time when  $r = r_0$ . As it stands, that assumption can be as accurate as we wish, since we have not yet specified either  $\mu$  or  $r_0$ . And if such a mass does appear then subsequent expansion will obey the equation

$$\dot{r}^2 = [2G(M+\mu)/r] - [2G\mu/r_0]$$

so that the cloud expands to a maximum radius given by

$$r_{\text{max}} = (1 + M/\mu)r_0 \sim (M/\mu)r_0 \text{ if } M \gg \mu$$

and then falls back. Since M is the mass interior to r, the outer regions expand to greater maximum radius than the inner regions.

In the Einstein-de Sitter cosmology with spherical symmetry we have

$$ds^2 = d\tau^2 - S^2(\tau)(dR^2 + R^2 d\Omega^2)$$

where

$$S \propto \tau^{2/8}$$
 and  $c = 1$ 

Transforming to locally flat space-time (for an observer at R=0) gives  $\mathrm{d} s^2 = \mathrm{d} t^2 - \mathrm{d} r^2 - r^2 \mathrm{d} \Omega^2 + (\mathrm{local} \ \mathrm{gravitational} \ \mathrm{effects})$  and the local gravitational effects may be included as a fourth order term such that

$$ds^{2} = dt^{2} (1 - 2GM/r) - dr^{2} - r^{2} d\Omega^{2}$$
 (1)

where M is the mass interior to r, proportional to  $r^3$  for uniform density. Equation (1) is the Newtonian result to first order, and the effect of a mass  $\mu$  at r=0 may be included by writing

$$ds^2 = dt^2[1-2G(M+\mu)/r] - dr^2 - r^2d\Omega^2$$

where M is now the mass of the cloud interior to r and not the total mass (cloud + core) interior to r.

It is possible to represent the solution of the local gravitational problem by a power series in the dimensionless parameter  $2G(M+\mu)/(rc^2)$  which is small for a local problem. The first term in the series is the Newtonian solution for the effect of  $\mu$  and may be used to good approximation provided that the second term in  $(GM/rc^2)$  is smaller than the first order term involving  $\mu$ , that is, if

$$2G\mu/rc^2\gg [2GM/rc^2]^2$$

This must hold for all r, including  $r = r_0$ , so

$$r_0\gg (M/\mu)2GM/c^2$$

if the problem is capable of solution by the Newtonian approximation. This corresponds to

$$r_{\text{m a x}} \gg (M/\mu)^2 2GM/c^2$$
 (2)

The argument here comes close to being circular, but seems fairly plausible. What we have found is that if the Newtonian approximation is valid, then the maximum radius reached by the expanding cloud with a retarded core at its centre satisfied inequality (2). Now, it is no secret that the whole purpose of this calculation is to come up with a mathematical description of something which looks like a galaxy. So we can put a typical galactic radius, say  $3\times10^{22}$  cm, into inequality (2) as the value of  $r_{\rm max}$ . If that is done, the inequality holds with a central mass  $\mu$  of  $10^9 M_{\odot}$  acting to regard the expansion of a cloud of mass  $M=10^{12}~M_{\odot}$ . With those figures, we can also set a limit of  $3\times10^{19}$  cm on  $r_0$ .

Putting all these figures together, we can say that for such a mass  $(10^9 M_{\odot})$  the value of  $r_0$  is much greater than the appropriate value of  $r_s$ . And, most important of all, we do indeed find that for galaxy-like objects the assumption that  $\mu \ll M$  is plausible.

All this does not, of course, prove that there must be collapsed objects at the centres of galaxies. But it suggests that the idea is not unreasonable. That is the best that can be hoped for for many astronomical ideas. The result is, however, suggestive in the light of the limit set on any central mass by Wolfe and Burbidge.

### Nature of the resulting galaxy

If we accept this result at face value it is simple to determine the optical appearance of the resulting galaxy. By considering shells of thickness dr at distances r from the centre of the gas cloud, we have a mean density at r given by

$$\rho_r = (\text{constant} \times r^{-2/3} \, dr) / (r^2 \, dr) \propto r^{-8/3}$$
 (3)

simply from dividing the mass of the shell by its volume. If stars form throughout the cloud we may take relation (3) as indicative of the number density of stars at r, and if all stars have the same luminosity function then the emissivity per unit volume at r is simply

$$E_r \propto r^{-8/3}$$

so that the intensity distribution measured by an outside observer will be

$$I_r = r E_r \propto r^{-5/8}$$

This is assuming an initially spherical distribution; but the resulting power law is in striking agreement with observations of elliptical galaxies and rather better than Hubble's well known empirical inverse square law.

Deviations from the spherically symmetric expansion may be considered by imposing a rate of strain tensor and a rotation of the cloud about the central mass. Hoyle and Narlikar8 have considered similar problems within the rather different framework of one of the C-field variants on the steady state model. They find that in such a situation the galaxy formed will be ellipsoidal with unequal principal axes, so that we would have something very similar to the elliptical galaxies observed today.

There remains the problem of spiral and irregular galaxies, and I do not wish to postulate any detailed model to account for their formation here (but see ref. 9). Evidence which suggested a two-component structure to our own Galaxy might, however, be taken as a hint that the spiral structure is a later appendage which has grown on to a retarded core type of central galaxy; and since rotation is only a second order effect which ought to be rapidly damped in the kind of expanding cloud envisaged, any evidence that elliptical galaxies are in general rotating would make the model outlined above

It is, however, striking that Wolfe and Burbidge say that any central black hole must be of mass less than  $10^9 M_{\odot}$  to

account for the structure of observed ellipticals, that the retarded cores hypothesis leads to exactly the same limit and that just this mass is required for the energy generation mechanism in radio galaxies. The model removes problems of how the collapsed objects formed, and the notion of such retarded cores as 'white holes' at the centre of galaxies encourages obvious speculations about the processes in QSOs, Seyferts and the like where matter seems to be pouring out into the Universe from local regions of space.

Even if it is necessary to adjust the boundary conditions to accommodate the existence of white rather than black holes at the centres of galaxies, that would be no worse than other ideas which have been put forward and which explain the energy produced in such objects in terms of new laws of physics and even the creation of matter.

### Towards gamma-ray lasers

Lowell Wood & George Chapline

University of California, Lawrence Livermore Laboratory, Livermore, California 94550

We suggest that two types of  $\gamma$ -ray laser are possible: a gently pumped variety utilising isomer separation and the Mössbauer effect, and a vigorously pumped kind using fast neutron excitation of compressed matter.

In this article we will discuss the operation of  $\gamma$ -ray lasers, namely devices which produce coherent, monochromatic, unidirectional electromagnetic radiation from de-excitation of excited nuclear levels. We will describe the necessary conditions for  $\gamma$ -ray laser operation, and consider some possible means of satisfying them.

The lifetimes for spontaneous γ-ray emission from excited nuclei range from  $10^{-17}$  to  $10^{-6}$  s if  $\Delta J$ , the angular momentum change in the transition, is small (≤2). For low energy transitions with large angular momentum changes, the lifetime can be much longer. For example, for  $\Delta J = 4$  and energy change ~ 100 keV, the radiative lifetime can be several years<sup>1</sup>. The existence of long lived excited nuclear states is intriguing from the point of view of achieving γ-ray laser action, because relatively modest pumping powers would be needed to produce population inversions. The opportunity of exploiting the multi-MeV binding energies of nucleons in nuclei to pump long lived

transitions between even high lying nuclear levels with the thermal neutron fluxes and charged particle accelerator beams is also notable. Moreover, the extraordinarily long life of transitions with large  $\Delta J$  makes it potentially possible to create nuclear population inversion through atom-by-atom physical segregation of the excited isomeric state from predecessor nuclei and other states of the same nucleus<sup>2-4</sup>. To take such advantage of long lived nuclear excited states, however, the spectral width  $\Delta v$  of the  $\gamma$ -ray emission line must be sufficiently small. The threshold inversion density for producing  $\gamma$ -ray laser action is proportional to  $\Delta v \tau_{spon}$ , where  $\tau_{spon}$  is the spontaneous radiative lifetime of the excited state. Thus a large value of  $\tau_{spon}$ must be compensated by a small value of  $\Delta v$ , in order that the density of the laser medium be that of a solid or less. If sufficiently small values of  $\Delta v$  cannot be achieved, then shorter lived excited levels, together with a density of the  $\gamma$ -ray laser medium higher than that of a solid, would be required.

Unlike X-ray line widths,  $\gamma$ -ray line widths are substantially unaffected by the properties of the medium, with one notable exception: 'recoil-less' emission in a crystal (the Mössbauer effect)5. Indeed, it is just the inability of the medium in which isomeric nuclei are embedded to mix excited nuclear states of high relative multipolarity significantly into ones of lower multipolarity which permits their extraordinary metastability.

Normally,  $\gamma$ -ray line widths are determined by either Doppler broadening (in a high temperature medium) or broadening arising from recoil of the emitting nucleus. The fractional spectral width  $\Delta \nu / \nu$  for thermal Doppler broadening is

$$(\Delta v/v)_{\text{Dopp}} \le 10^{-8} (\theta/A)^{1/2}$$
 (1)

where  $\theta$  is the temperature of the medium (keV), and A is the mass number of the nuclei of interest. The fractional line width caused by recoil of the emitting nucleus is

$$(\Delta v/v)_{\text{recoil}} = \overline{h}\omega/2Mc^2 \approx 10^{-5}k \tag{2}$$

where k is the photon energy in MeV and M is the mass of the recoiling nucleus. Except for the special circumstance of recoil-less emission, the recoil broadening sets a lower bound on the  $\gamma$ -ray line width. In the case of recoil-less emission, the emitting nucleus is bound in a crystal whose Einstein oscillator energy is at least comparable to the kinetic energy acquired by an isolated,  $\gamma$ -ray emitting nucleus. The recoil broadening of such a crystal is negligible because substantial parts of it can take up the recoil momentum. The spectral widths in such cases can be much closer to the natural widths;  $\gamma$ -ray line widths  $\Delta v \sim 10^5$  Hz have been observed for transitions with  $\tau_{\rm spon} \sim 10^{-6}$  s by Mössbauer spectroscopic techniques. By growing very pure crystals with minimal line-broadening lattice stresses respectively. The smaller emission line widths should be attainable with long lived nuclear isomers.

These considerations suggest two possible classes of  $\gamma$ -ray laser: (i) those which operate on allowed (E1 or M1) or weakly forbidden (E2 or M2) transitions, necessarily under vigorous pumping conditions, with  $10^{-5} \lesssim \Delta v/v \lesssim 10^{-3}$ ; (ii) those which operate on forbidden transitions (for example, E3 or M3), in an environment such that  $\Delta v/v < 10^{-15}$  (refs 7 and 8). In (i), the threshold inversion densities will generally be higher than solid densities, so the vigorous pumping must usually be accompanied by compression of the  $\gamma$ -ray laser medium. In (ii), attainment of the small values of  $\Delta v$  needed require recoil-less emission, so the laser medium must be gently pumped, at a temperature less than the Debye temperature<sup>2,3</sup>.

As noted previously<sup>4</sup>, it is not necessary to use cavity-bounding mirrors to produce  $\gamma$ -ray laser action. Indeed, the extremely high minimum fluxes and fluences of a pulsed  $\gamma$ -ray laser would destroy such reflectors. The nature of gently pumped devices may allow the use of Bragg diffraction-type<sup>9,10</sup> cavity mirrors; however, high intrinsic losses ( $\geq 2-3$  dB per pass) make them only marginally useful. We therefore take axial superfluorescence to be a necessary condition for  $\gamma$ -ray laser operation, and (quite conservatively) require

$$\alpha l \gtrsim 30$$
 (3)

where  $\alpha$  is the net gain and l the length of the cylindrical, population-inverted medium. Concurrently, in order to avoid radial superfluorescence, the diameter d of the laser medium must be small compared with its length,

$$d \ll l$$
 (4)

but at least comparable to  $(\lambda l)^{1/2}$  and large relative to  $(\lambda l \alpha)^{1/2}$ , in order to avoid severe diffraction losses. In the absence of losses, equation (3) implies that the net inversion density  $N^*$  must satisfy (L.W., G.C., S. Slutz and G. Zimmerman, UCRL75184, 1974).

$$N^* \gtrsim 30 \left(8\pi/\lambda^2 \left(\Delta \nu \tau_{spon}/l\right)\right)$$
 (5)

where  $\lambda$  is the  $\gamma$ -ray wavelength. Equation (5) is the threshold condition for laser action. We now discuss how this threshold condition might be satisfied for each of the two classes of  $\gamma$ -ray laser.

### Vigorously pumped lasers

We consider, as a possible technique for population inversion, the pumping of nuclear excited states by very high neutron fluxes. The  $\gamma$ -ray laser would consist of a DT thread of milligram mass, loaded with perhaps 1 atom-% of the higher Z nuclei on whose neutron-excited, population-inverted metastable levels the laser will depend for its operation. (Lasing might also take place between levels of population-inverted capture, spallation or fission product nuclei.) Recalling that characteristic 14-MeV neutron excitation/break-up cross sections on such nuclei are 10-24 cm<sup>2</sup>, we note that time-integrated neutron fluxes in compressed-and-ignited fibres of the order of 1024 cm-2 may be obtained over picosecond time scales by compression to densities of 10<sup>4</sup> g cm<sup>-3</sup> (comparable to those proposed for a laser controlled thermonuclear reactor<sup>11</sup>). The corresponding fluxes (> 1035 cm-2 s-1) are more than sufficient to give a high probability of excitation/break-up on time scales characteristic of allowed  $\gamma$ -ray transition of energies < 1 MeV.

The threshold inversion density is  $1.2 \times 10^{28} k^3$  cm<sup>-3</sup>, assuming l=1 cm,  $\tau_{\rm apon}=10^{-12}$  s and taking  $\Delta v/v=(\Delta v/v)_{\rm popp}\simeq 10^{-3}$ , from equation (1), using a typical fusion microexplosion ion temperature of  $\sim 100$  keV and  $A\simeq 10^2$ . We conclude that it is possible to achieve  $\gamma$ -ray laser action with  $k\lesssim 0.2$  in a suitable cylindrical fusion microexplosion for which the space-time power programming of the implosion-driving laser pulse streaked the microexplosion along such a fibre at about the speed of light. Laser pulses of about  $10^5$  J per mm of length would apparently be required to implode and ignite the fusionable material which produces the neutron fluxes needed to pump the emitting nuclei.

Of course, attainment of large inversion densities is not necessarily sufficient for the attainment of laser action, because of  $\gamma$ -ray laser losses in the medium. In order that the gain due to stimulated emission of a vigorously pumped  $\gamma$ -ray laser exceeds the loss due to Compton scattering, the dominant opacity mechanism,

$$\tau_{\rm spon} < 10^{-14}/(\overline{Z}k^3) \, {\rm s}$$
 (6)

where  $\overline{Z}$  is the average atomic number of the laser medium. This is an extremely stringent condition and indeed, there are no  $\gamma$ -ray transitions with k < 0.2 presently known to us which satisfy this condition.

Table 1 Data for a gently pumped γ-ray laser						
k(MeV)	λ (A)	$\lambda^2/8\pi$ (barn)	Δν <sub>max</sub> (Hz)	Δν <sub>mln</sub> (Hz)	ζ <sub>min</sub>	
0.01	1.24	6 × 10°	30.0	1.0	30	
0.05	0.248	$2.4 \times 10^{5}$	1.0	0.01	100	
0.10	0.124	$\begin{array}{c} 6\times10^4\\ 600\end{array}$	0.3	0.001	300	
1.00	0.0124		0.003	0.0001	30	

The Table shows, as a function of  $\gamma$ -ray wavelength, the approximate maximum allowed line width  $\Delta v_{max}$  for a gently pumped  $\gamma$ -ray laser  $(l=3 \text{ cm}, \tau_{spon}=10^4 \text{ s})$ , the internal conversion-limited minimum line width, assuming  $\tau_{spon}=10^4$ ,  $\alpha=10 (0.1/k)^3$ , and the minimum figure of merit  $\zeta \equiv \sigma_{max}/(1+\alpha) \sigma_{abs}$  needed to operate at the maximum allowed width.

### Gently pumped lasers

We have noted that, to exploit recoil-less emission, the excited nuclei must be incorporated in a crystal lattice which is kept sufficiently cool<sup>3</sup>. This suggests that the nuclei must be excited before they are assembled into a crystal lattice. As a practical matter, it seems that nuclei may be excited and then embedded in a recoil-less environment (for example, irradiated in a nuclear reactor, separated from other isotopes and nuclei of the same A and Z but different excitation levels, and then crystallised into a thread of suitable composition) only on time scales > 10<sup>2</sup> s; so we are compelled to use relatively longlived nuclear isomeric states. Moreover, the strengths of chemical bonds of most substances imply that substantially recoil-less environments exist only for  $k \leq 0.1$ . We are therefore most interested in E3 or M3 transitions. We note that the collective nature of these excited nuclear states implies large isomer shifts of electronic spectral lines12, comparable to isotope shifts, which greatly facilitates isomer separation by photochemical/photophysical means (ref. 13 and T. Axelrod, A. Bernhardt, T. O'Leary, J. Marling, R. Keeler and L. W., UCRL74904, 1973).

acoustic isolation would also be required to minimise axial velocity gradients in the medium. Indeed, laser action itself will lead to a relatively slight, variable acceleration of the medium, which is minimal if the system emits collectively. Such super-radiant emission<sup>15,16</sup> is likely ,since the 'cooperative length' for collective de-excitation,  $I_c = (2\pi c \tau_{cp,th} / \lambda^2 N^*)^{1/2} \gg l$ .

Internal conversion is an important limitation on gently pumped  $\gamma$ -ray lasers because of the high multipolarity and relatively low energy of the transitions of interest. For E3 or M3 transitions, the (dominant) K-shell internal conversion coefficient  $\alpha_{\rm K}$  is of the order of 10 for  $k\simeq 0.1$ . Thus our assumed radiative lifetime  $\tau_{\rm apon}$  of  $10^4$  s corresponds to an actual half life  $\tau_{1/2}\simeq 20$  min, which would be the maximum time allowed for isomeric state separation, followed by crystal formation and conditioning. Since  $\tau_{1/2}=(\alpha+1)$   $\tau_{\rm apon}$ , where  $\alpha=\alpha_{\rm K}-\alpha_{\rm L}+\ldots$  is the total internal conversion coefficient, we also have  $\Delta \nu > (\alpha+1)/\tau_{\rm spon}$ .

Photoelectric absorption also severely limits the available  $\gamma$ -ray laser parameter space. The photoelectric cross section per atom in cold matter,  $\sigma_{\rm photo}$ , is of the order of  $Z^4$   $(0.01/k)^3 \times 10^{-26} \, {\rm cm}^2$ . This photoelectric cross section may be quite large

	Table 2 Nuclear isomers considered most promising for gently pumped γ-ray laser action								
Isomer	k(MeV)	λ (Å)	σ <sub>max</sub> (barn)	σ <sub>abs</sub>	α	ζ	τ <sub>1/2</sub> (min)	Class	Production

 $\sigma_{max}$  is the approximate maximum stimulated emission cross section possible,  $\sigma_{abs}$  the photoelectric absorption plus Cc mpton scattering cross sections at the transition energy per atom,  $\alpha$  the total internal conversion coefficient and the figure of merit of the isomer,  $\zeta = \sigma_{max}/(1 + \sigma)$   $\sigma_{abs}$   $\tau_{1/2}$  the excited state half life. Also shown are the multipolarity of the radiative decay and the most promising means of production of the isomer, including the fractional natural abundance and thermal neutron capture cross section (in barns) to the isomeric state of its precursor.

\*\*OpenCo\*\*, \*\*PamSe\*\* and \*\*PamSe\*\* are considered especially interesting as they are formed substantially population-inverted.

Maximum values of  $\Delta v$  which allow attainment of threshold  $\gamma$ -ray laser inversion densities below those of a solid (5  $\times$  10<sup>22</sup> cm<sup>-3</sup>) are shown in Table 1, assuming  $\tau_{\rm spon}=10^4$  s and l=3 cm. Although required values of  $\Delta \nu$  are smaller than the smallest so far measured to present<sup>6</sup> (≈ 10<sup>5</sup> Hz), they are much larger than the typical natural widths. It therefore seems reasonable to expect that the required values of  $\Delta v$  may be attained, using carefully prepared crystals (such as metal whiskers which have only a single axial screw dislocation and are effectively perfect) to minimise inhomogeneous line broadening caused by lattice irregularities. Even in such crystals, however, there would be inhomogenities arising from differences between the upper and lower states of the emitting nuclei. For instance, the magnetic dipole-dipole interaction between neighbouring nuclei can be ~ 103 Hz and would result in disasterously large line broadening in even a perfect crystal. Fortunately, such interactions will time-average to much smaller values, producing the required line narrowing, if the nuclear spin temperature is not too low. Such nuclear spin temperatures ( $\gtrsim 10^{-6} \text{ K}$ ) may be attained by many means, if necessary, such as the application of radiofrequency pulses to the  $\gamma$ -ray laser medium<sup>14</sup>. In order to avoid line shifts caused by external magnetic and electric fields, electric field gradients across the laser medium must be kept below 107 V cm<sup>-1</sup> and ambient magnetic field intensities must be  $\lesssim 10^{-4}$  gauss. Also, the second-order Doppler effect and long wavelength phonons may cause significant line broadening in the laser medium, because of strain-inducing thermal gradients and microscopic scale velocity gradients, respectively, unless the ambient temperature is kept below 10 K.

The line shifts induced by gravitational potential difference across the  $\gamma$ -ray laser medium require that these lasers be operated within an angle  $(c^2/gl)$   $(\Delta v/v) \simeq 10^{-4}$  rad of the perpendicular to the local gravitational gradient. Likewise,

compared to the stimulated emission cross section. For example, the stimulated emission cross section corresponding to the maximum allowable line width is  $\approx 10^2$  barn, whereas the photo-electric cross section may be > 103 barn. For a laser operating with bandwidth  $\Delta v$ , the cross section for stimulated emission will exceed that for photoelectric absorption only if  $Z \lesssim 600k^{1/4}$  ( $\Delta v \tau_{spon}$ )<sup>-1/4</sup>. This relation states that, for low photon energies produced by nuclei of high Z, it will be necessary to achieve operating bandwidths approaching the minimum useful widths  $\simeq \alpha/\tau_{ip\cdot n}$ . This suggests a figure of merit for nuclear isomeric candidates:  $\zeta \equiv \sigma_{max}/(1+\alpha)\,\sigma_{abs}$  where  $\sigma_{max}=\lambda^2/8\pi$  and  $\sigma_{at}$  is the sum of the photoelectric and Compton scattering cross sections. This figure of merit is obviously the multiple of the minimum attainable width at which the  $\gamma$ -ray laser will still have a net gain, if the nuclei of the medium are completely populationinverted. Incompletely pure media reduce this figure of merit proportionally to the fractional population inversion. Because  $\zeta$  is, generally speaking, never very large we are not optimistic about proposals<sup>7,8</sup> for using isomers with  $\tau_{1/2} > 10^6$  s.

Photoelectric absorption and internal conversion lead to heating of the gently pumped  $\gamma$ -ray laser medium that might destroy the recoil-less narrowing of the emission line necessary for laser action. For isomeric states with half lives  $>10^{2}\,\mathrm{s}$ , however, the heat generated by internal conversion can be easily removed on the time scales over which laser action occurs by thermal conduction cooling, if the radius of the laser medium is  $\leq 10~\mu\mathrm{m}$ . Heating by photoelectrons in a fibre 1  $\mu\mathrm{m}$  in diameter resulting from a  $\gamma$ -ray laser pulse of length  $\tau_{\mathrm{pulse}}$  s is of the order of  $10^{6}k~(\sigma_{\mathrm{photo}}/\sigma_{\mathrm{stlm}})/\tau_{\mathrm{pulse}}$  eV s<sup>-1</sup> per atom, where  $\sigma_{\mathrm{stlm}}$  is the stimulated emission cross section. A laser medium self-heating rate of  $10^{2}$  eV s<sup>-1</sup> per atom is acceptable (resulting in operating temperatures of 10K for the medium

and implies that  $\sigma_{\rm stlm}/\sigma_{\rm photo}$  must exceed  $10^3 k/\tau_{\rm pulse}$ . Since  $\tau_{\text{pulse}}$  must be shorter than  $\tau_{1/2}$ , the isomeric state half life, this implies that  $\sigma_{\rm stlm}/\sigma_{\rm photo}$  must be greater than  $10^3 k/\tau_{1/2}$ . For  $\tau_{1/2} > 100$  s, this criterion will be satisfied for k < 0.1 if  $\sigma_{stim} > \sigma_{phot}$  , which is the basic net gain condition for  $\gamma\text{-ray}$ lasers (as  $\alpha \gg 1$ ). Thus photoelectric self-heating of the medium during laser action is not a serious problem, if  $\tau_{1/2} \gtrsim 100s$ .

Because of the difficulties of producing small  $\gamma$ -ray line widths in bulk samples, Goldanskii and his colleagues<sup>17-19</sup> see promise only in pulsed (≤ 10<sup>-2</sup> s) nuclear population inversion, where larger values of  $\Delta v$  would be permitted. While we concur with the Goldanskii-Kagan analysis of the requirements on  $\gamma$ -ray laser action in the half life regime 10<sup>3.5±1</sup>, we see these requirements as attainable through extant laser and semi-conductor technologies, and thus do not share their pessimism in these respects. In contrast, scrunity of essentially all nuclear data published through 1972 (rcfs 20, 21 and R. Haight, private communication) does not indicate the existence of even one candidate nuclear species for the nuclear explosion-pumped approach advocated by the Goldanskii-Letokhov school. Such a nucleus must have an excited state half life of > 10<sup>-6</sup> s (for substantial thermal neutron fluxes cannot be generated through fast flux moderation on shorter time scales) but  $\leq 10^{-2}$  s (by the Goldanskii assumptions on the required fractional line width), and have a thermal capture cross section of ≥ 10-20 cm<sup>2</sup> (to prevent overheating of the laser medium associated with thermal neutron fluences of  $\gtrsim 10^{20}$  cm<sup>-2</sup>). Indeed, the <sup>181</sup>Ta nucleus nominated for such a role 17,18 is now known to have several times too small a cross section for neutron capture, though it is the most apt choice we have identified so far. In addition, realistic evaluation of the magnitude of the pulsed time-integrated neutron fluxes to which a medium may be subjected and still show recoil-less narrowing indicates that the estimate of 10<sup>20</sup> cm<sup>-2</sup> is optimistic by at least a factor of three, when heating by scattering of the incompletely moderated (epithermal) neutron spectrum and other nuclear explosion-associated effects (prompt gamma rays, hydrodynamic and thermal conduction energy transport, for example) are considered. The nuclear explosion-pumped  $\gamma$ -ray laser advocated by Goldanskii and collaborators thus fails of attainability by at least an order of magnitude, in the most favourable case for it.

### Realisation of gently pumped lasers

An attempt to operate a  $\gamma$ -ray laser might commence by irradiation of an appropriate target in a high flux nuclear reactor or charged particle accelerator for several nuclear isomeric state lifetimes, so that saturation quantities of isomeric nuclei would be produced. The target might then be rapidly inserted into an atomic beam oven, and the nuclear isomeric state and its daughter ground state nuclei efficiently evaporated into a well collinated atomic beam from which the isomeric state atoms could be routed via any of several photophysical processes (ref. 13, UCRL74904 and ref. 22) into a very small channel (width  $\sim 1 \mu m$ , length 0.1-1cm) machined into a heat sink over which the isomeric beam component rather uniformly loaded. The heat sink would then be rapidly levelled, acoustically isolated, magnetically shielded and cooled to liquid helium temperatures, whereupon y-ray lasing action would commence.

As a particular example, we consider 60Co, whose isomer decays in 10.7 min through a 59-keV M3 transition to a long lived (5.2 yr) ground state and which has the notable property of being born substantially population-inverted, because of the relatively large neutron capture cross section into the isomeric state and the comparatively small statistical weight of this state. This isomer can be produced in milligram quantities on minute time scales by (high flux) reactor thermal neutron irradiation of naturally occurring 59Co. The 60Co and 60 mCo can be separated from <sup>59</sup>Co by γ-cascade-recoil ejection from thin foils at the time of formation. Assembly of the separated isomeric fraction

into a pure, strain-free cylindrical crystal (for example, a metallic cobalt whisker) would be followed by very rapid annealing and purification from impurities generated by β-decay in the panned focal spot of a laser beam, exploiting the very short thermal relaxation times of these whiskers, γ-ray lasing would commence as the required environmental conditions were attained. The relative width that must be achieved to obtain  $\gamma$ -ray laser action for this material is  $\sim 3 \times 10^{-20}$ .

Some nuclei we consider to be candidates for gently pumped  $\gamma$ -ray laser action are given in Table 2. A more complete list of candidate nuclei has been prepared by L. P. Somerville (UCLL Memo 5574-220). Many variations on this basic theme are obvious, some of which are to be preferred for particular nuclear isomers (for example, those with Z different from that of their parent nuclei, such as may be readily produced with accelerator beams).

### Molecular structure

We have briefly reviewed the salient physical conditions limiting  $\gamma$ -ray laser operation, taken note of the two basic types of laser, and described how each type might operate. Such lasers seem to be candidates for producing coherent photon beams with  $h\omega \gtrsim 10$  keV, though quite substantial technological challenges must be met in realising them. Operation of  $\gamma$ -ray lasers with  $h\omega \gtrsim 100$  keV, however, seems exceedingly difficult. Timebandwidth limitations force gently pumped lasers to emit their pulses over multi-second time scales; that is, gently pumped γRLs would be quasi-c.w. sources of extremely coherent and monochromatic radiation with 0.1 Å  $< \lambda < 1$  Å. It seems clear that such sources will be extremely useful in the basic and applied sciences, particularly in the determination of the structure and composition of large molecules.

We acknowledge discussions with Edward Teller, Robert Haight, Morton Weiss, John Nuckolls, and Jonathan Katz (who also carefully examined the manuscript). We also acknowledge private communications with V. Goldanskii, V. Letokhov and R. Khokhlov. We thank L. P. Somerville for assistance in surveying the nuclear data literature. This research was carried out under the auspices of the United States Atomic Energy Commission.

# Bacterial mutation affecting T4 phage DNA synthesis and tail production

### Lee D. Simon & Dale Snover\*

### A. H. Doermann

University of Washington, Seattle, Washington 98105

A new type of host defective Escherichia coli mutant, hd590, is described. T4+ infection of this mutant results in (1) an abnormally low rate of T4 DNA synthesis that is constant throughout the latent period; (2) relatively low amounts of specific late T4 proteins; (3) the production of empty T4 heads, but not of tails or tail fibres. Two types of T4 mutants, one in T4 gene 31 and the other near T4 gene 39, overcome the hd590 block.

Investigators examining the role of the host cell in phage production have isolated several host mutants that permit phage adsorption but block virus production. Three principal types of 'host defective', hd, cells in which T4 production does not occur have been reported. In the first, T4 DNA synthesis and tail production are normal, but phage capsids do not assemble<sup>1-3</sup>. T4 heads normally assemble on the host cell inner membrane<sup>4</sup>, and one T4 gene product, P31, is known to affect the association of head proteins with the cell membrane<sup>5</sup>. Some T4 mutants in gene 31 can overcome the block in head assembly in the first type of hd bacterium<sup>1-3</sup>.

The second principal type of hd bacterium, a mutant resistant to rifamycin, seems to possess an altered RNA polymerase<sup>6</sup>. T4 infection of this cell results in a slight delay in T4 DNA and late protein synthesis, as well as in a slight delay in the shutoff of host mRNA synthesis. Characteristics of T4 mutants which can overcome this type of hd block have not been reported.

The third type of *hd* bacterium blocks the production of functional tail fibres, producing T4 particles which lack the normal complement of long tail fibres<sup>7</sup>. These fibreless phages can be activated by the *in vitro* addition of long tail fibres.

We describe here a new type of hd mutant, E. coli hd590, which blocks T4 production. After wild-type T4 (T4+) infection of hd590, T4 heads are made, but are not filled with DNA. Tails are not made, and the rate of T4 DNA synthesis is abnormally low for the duration of the latent period. Two types of T4 mutants (T4go590) able to form plaques with high efficiency on hd590 have been isolated and characterised. One type of T4 mutant able to overcome the hd590 block seems to map in gene 31; the other type seems to map in a different region of the T4 genome, near gene 39.

### E. coli hd590 and T4 production

Escherichia coli hd590, a nitrosoguanidine-induced mutant of E. coli B011', was selected for its inability to function as a normal host for T4 and T6 bacteriophages. Uninfected hd590 cells grow well in complex media such as tryptone broth. In a minimal medium, however, such as LSTG (described in Fig. 3 caption) or M9 (glucose, salts, phosphate) hd590 bacteria fail to divide; instead, they form long, fragile filaments. Addition of casamino acids, vitamins, dipeptides, tryptophan or a mixture of deoxynucleosides to the minimal medium did not stimulate

hd590 cell division. Supplementation of minimal medium with both casamino acids (10 µg ml<sup>-1</sup>) and the mixture of deoxynucleosides (5 µg ml<sup>-1</sup>) permitted slow growth and division of hd590 cells.

More than 90% of the hd590 bacteria lost their ability to form colonies within 5 min after addition of T4+ particles at an average multiplicity of infection (MOI) of 5 phages per cell. Although T4+ particles attached to and killed hd590 bacteria with normal efficiency, infection of these bacteria by T4+ particles did not lead to the production of plaque-forming progeny phages (Fig. 1). The block in T4+ production in hd590 was independent of temperature between 20° C and 43° C. In Fig. 1 and in most subsequent figures, T4+ infections

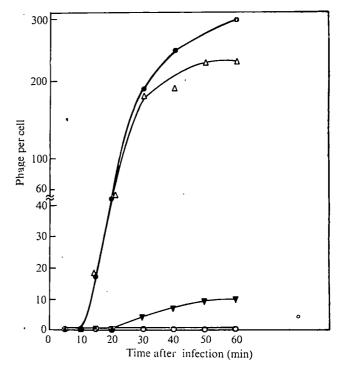

Fig. 1 Phage production and cell killing resulting from T4 infection of E. coli hd590 and E. coli B011'. ♠, B011'; T4+; △, B011'; T4go590-1; ○, hd590; T4+; ▼, hd590; T4go590-1. Mid-log phase bacteria were used in these and in all other experiments described in this paper. T4+ refers to T4D phages. Bacteria growing in broth (10 g Bacto-tryptone, 5 g NaCl, 1,000 ml H<sub>2</sub>O) at 37° C were infected with the appropriate T4 particles (MOI = 5) and 5 min later they were superinfected with the same type of T4 particles (MOI = 5). Viable cell counts were made just before infection and at various times thereafter. Anti T4 serum was added 8 min after infection; 10 min after infection the bacteria were diluted × 10⁴ to prevent inactivation of progeny phages by the antiserum. At various times, samples were removed from the infected cultures; they were exposed to chloroform to lyse the bacteria; they were then plated to determine phage production. Both B011' and hd590 are readily killed by the T4 particles; only B011', however, produces normal yields of T4 particles.

<sup>\*</sup> Present address: Pennsylvania State University, School of Medicine, Hershey, Pennsylvania 17033.

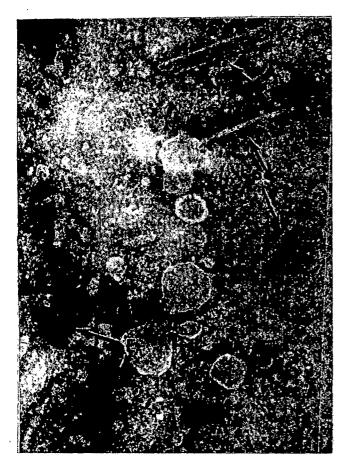

Fig. 2 Electron micrograph of a negatively stained lysate from T4<sup>+</sup>-infected hd590 bacteria. E. coli hd590 cells were infected (MOI = 5) and superinfected (MOI = 5) with T4<sup>+</sup> particles. One hour after infection chloroform and pancreatic DNase (10 g ml<sup>-1</sup>) were added to the culture. Samples of the lysate were then negatively stained with 1% phosphotungstate at pH 7.0 and examined in the electron microscope. The lysate contained empty heads (E) polysheath (PS) and polyheads (PH). (Magnification is approximately × 55,000.)

of B011', the parent *E. coli* strain, are shown as control experiments.

Electron microscopic studies of T4 production after T4+ infection of *E. coli hd* 590 show only empty phage heads, polysheath and polyheads in negatively stained lysates (Fig. 2). Very few tails were observed, and they probably derived from the input phage preparation. The presence of polysheath in the T4+-infected *E. coli hd* 590 lysates indicates that at least some tail proteins were made, although the polysheath occured in a smaller amount than would be expected from a typical T4 mutant blocked in baseplate or tail core assembly.

In agreement with the observations of lysates, electron microscopic examinations of thin sections through T4+-infected  $E.\ coli\ hd590$  cells showed only empty heads in the central regions of the bacteria. In addition, lumps of head precursor material and  $\tau$  particles<sup>4,5</sup> were evident on the bacterial membrane (data not shown). Although empty heads were the predominant head-related structures seen in thin sections, polyheads, resembling tubular  $\tau$  particles, were also visible. Both polyheads and  $\tau$  particles, with their long axes extending towards the interior of the cell, appeared to be bound to the cell membrane.

Using sodium dodecyl sulphate (SDS)-acrylamide gel electrophoresis, we analysed the proteins made after T4+ infection of *E. coli hd590*. Normal T4 infection blocks the synthesis of host cell proteins soon after infection; therefore, T4 proteins were specifically labelled with radioactive precursors. Particular gene products were identified by the use of specific T4 amber mutants which block the synthesis of specific proteins. As Fig. 3 shows, bands representing many late T4 proteins

(such as the major head protein, p23 and the tail sheath protein, p18) were present in the T4+-infected *E. coli hd5*90 sample; however, bands corresponding to the gene 7 and gene 34 products appeared to be very faint or absent. These gene products are normally parts of the phage baseplate and tail fibre structures, respectively<sup>8</sup>. Several other T4 proteins also seemed to be missing or to be made in relatively small amounts. A few bands not present in the control sample (T4+: *E. coli* B) were seen in the T4+: *E. coli hd5*90 infection. It is unclear whether these new bands represent fragments of proteins synthesised in normal T4 infections, host proteins or early proteins which have not been turned off.

Since electron microscopy showed that phage heads were assembled but not filled with DNA in T4+-infected E. coli hd590 bacteria, we compared the rates of T4 DNA synthesis after phage infection of E. coli hd590 and E. coli B011' at 37° C. The determinations were made by measuring the incorporation of H³-thymidine into trichloroacetic acid (TCA)-precipitable material during 2-min pulses given to samples of the infected cultures. As Fig. 4a shows, the rate of DNA synthesis in T4+ infected E. coli hd590 cells was much lower than the comparable rate in infected E. coli B011' cells. The maximal rate of DNA synthesis in T4+-infected E. coli hd590 bacteria was approximately 13% of the maximal rate in similarly infected E. coli B011'.

Figure 4b shows that the amount of newly synthesised T4 DNA within T4+-infected hd590 bacteria was much lower than that in T4+-infected B011' cells. These data also indicate that DNA synthesis in T4+-infected E. coli hd590 began at approximately the normal time, although at a reduced rate which remained constant throughout the latent period (Fig. 4a and b).

In other experiments (data not shown) we found that the DNA which accumulates in T4+-infected hd590 cells sediments more rapidly than the 63S DNA from mature T4 particles. This rapidly sedimenting DNA is characteristic of certain T4 infections in which head filling is blocked<sup>10</sup>.

In an effort to find reagents which could promote T4 production in hd590 cells, we observed that the addition of low concentrations of EDTA to T4+ infected hd590 samples significantly increased the yield of T4 particles (Fig. 5). We added 0.0002 M EDTA to mid-log phase E. coli hd590 cells in tryptone broth at the time of infection with T4+ particles and found a marked increase in the production of progeny phages. This result was essentially the same whether the EDTA was added at the time of infection, 2 min before infection or 8 min after infection. When we increased the EDTA concentration to 0.1 M or higher, we observed no increase in phage production, presumably because the infected cells were damaged by the EDTA.

We also observed that addition of EDTA could alter the level of DNA synthesis in T4+-infected hd590 and B011' cultures (Fig. 5). Although 0.0002 M EDTA had little, if any, detectable effect on DNA synthesis in either sample, higher concentrations of EDTA markedly reduced T4 synthesis in the B011' controls and markedly increased T4 DNA synthesis in the hd590 samples. Thus, the T4+-infected hd590 and B011' samples showed nearly the same levels of DNA synthesis when exposed to 0.0001-0.005 M EDTA.

### T4 mutants

T4 mutants (go590) able to plate on E. coli hd590 occur spontaneously at a frequency of about 10-8. One such phage mutant, designated T4go590-1, was studied in detail. We investigated the physiology of a T4go590-1 infection of E. coli hd590. Although T4+-infected E. coli hd590 cells yielded an average of less than 0.01 progeny phage per cell, T4go590-1-infected E. coli hd590 cells yielded an average of 10 phage particles per bacterium (Fig. 1). This burst size, although sufficient to cause formation of plaques, is lower than would be expected of a completely normal infection. Negative staining of hd590 cells lysed by chloroform 20 min after T4go590-1 infection showed a pattern similar to that seen 20 min after T4+-infection of the cells, with empty heads, polyheads and polysheath. At

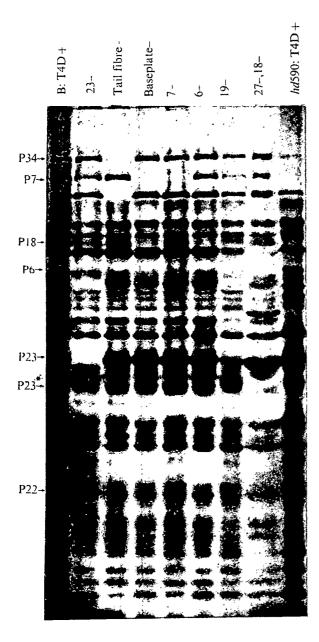

Fig. 3 Autoradiograph of an SDS-acrylamide gel showing the phage proteins in T4<sup>+</sup>-infected hd590 cells. Since E. coli hd590 (su+) do not grow well in minimal medium, hd590 and E. coli B (su) were grown in tryptone broth to 4  $\times$  10<sup>8</sup> cells ml<sup>-1</sup>; the bacteria were pelleted and resuspended in LSTG medium (6.4 ml 0.1 M KH<sub>2</sub>PO<sub>4</sub>, 1.6 ml 0.1 M Na<sub>2</sub>SO<sub>4</sub>, 2.0 ml 0.5 M MgCl<sub>2</sub> 100 ml 10  $\times$  low salts, 100 ml 1.0 M Tris, pH 7.4, 100 ml 20% glucose ,H<sub>2</sub>O to 1,000 ml; 10  $\times$  low salts contains 5.4 g NaCl, 3.0 g KCl, 11.0 g NH<sub>4</sub>Cl, 10 ml 0.1 M CaCl<sub>2</sub>, 10 ml 0.1 M FeCl<sub>3</sub>. H<sub>2</sub>O to 1,000 ml) containing 1% (v/v) tryptone broth. The two cultures were then infected (MOI = 3) and superinfected (MOI = 3) 7 min later with T4<sup>+</sup> particles. A mixture of amino acids— $^{14}$ C (100  $\mu$ Ci ml<sup>-1</sup> for hd590 and 20  $\mu$ Ci ml<sup>-1</sup> for B) and containing 100 ml<sup>-1</sup> for hd590 and 20  $\mu$ Ci ml<sup>-1</sup> for B) and -35S (100 μCi ml-1 for hd590 and 20 μCi ml-1 for B) methioninewas added to the cultures 12 min after infection. The bacteria were pelleted 35 min after infection; the pellets were heated to 100 for 2 min in 1% SDS and 1% β-mercaptoethanol. Other E. coli B cultures, growing in LSTG medium, were infected with various T4 amber mutants and were then treated in the same way as the previously described *E. coli* B sample. The amber mutants used for this gel were T4amH11 (23<sup>-</sup>), T4amXF18 (baseplate<sup>-</sup>), T4amX4E (tail fibre<sup>-</sup>), T4amN102 (6<sup>-</sup>), T4am B16 (7<sup>-</sup>), T4amN120amE18 (27<sup>-</sup>, 18<sup>-</sup>) and T4amE1137 (19<sup>-</sup>). The denatured proteins were run on SDS-acrylamide (10%) slab gels<sup>8</sup> for 5.5 h at 80 V after which the gels were dried. Autoridio for 5.5 h at 80 V, after which the gels were dried. Autoradiographs were then made to allow visualisation of the protein bands. Columns labelled BT 4+ and hd590:T4+ indicate E. coli B and E. coli hd590 respectively infected with T4+ phages. All other columns are infections of E. coli B by the appropriate T4 amber mutant.

later times, however, intact phage particles appeared in the T4go590-1-infected samples, but not in the T4+-infected E. coli hd590 samples.

To determine whether the pattern of phage DNA synthesis in T4go590-1-infected E. coli hd590 differs from that observed after T4+ infection, we measured thymidine incorporation into TCA-precipitable material at various times after the infection of cultures of E. coli hd590 bacteria with either T4go590-1 or T4+ phages. The data from this experiment (Fig. 4a) suggest that until 26 min after infection, the rates of DNA synthesis in T4go590-1 and in T4+-infected E. coli hd590 bacteria are similar. After 26 min, however, the rate of phage DNA synthesis in the T4go590-1 infected culture started to increase whereas there was no comparable increase in the T4+-infected E. coli hd590 culture. Sixty minutes after infection, the rate of DNA synthesis in the T4go590-1-infected hd590 culture is about double the rate in the T4+-infected hd590 culture.

The map position of T4go590-1 was determined from analysis of a series of crosses performed as described before<sup>11</sup>. Genotypes of the progeny phages from such crosses were identified using method II of Doermann and Boehner<sup>12</sup>, but adopting modifications appropriate to the particular mutants involved (details in legend for Table 1). The first cross used T4go590-1 as one parent and, as the second, a strain carrying mutations in the following 12 genes: e, 5, 11, 24, 48, 34, 37, ac, rIIB, 39, 43, and 46. Data from more than 1,000 progeny phages showed that the recombination frequency of go590-1 with other markers was lowest with amN85 (gene 48) and increased progressively for markers in both the clockwise and the counterclockwise directions from gene 48. The maximum value was attained with amN130 (gene 46). In cross 2 therefore, the second parent was replaced by a phage with markers in genes 25, 26, 51, 27, 29, 48, 31 and 34. Although 1,050 progeny were scored and both complementary recombinants found with all other markers, not a single recombinant was found for go590-1 and am N54N (gene 31). Cross 3 involved parents with makers in 7 genes (29, 48, 30, 31, 32 and 34), and analysis of 1,118 progeny phages again failed to uncover a single recombinant between go590-1 and amN54 although all other recombinant classes were recovered with reasonable frequencies. Thus, among more than 2,000 cross-progeny phages neither the doubly mutant nor the wild-type recombinant for these two markers was found. It must be concluded that go590-1 is very close to amN54 in gene 31 or perhaps represents a multisite mutation whose ends overlap the site of the amN54 mutation.

With the possibility of a multisite mutation in mind, recombination between go590-1 and a second amber mutation in gene 31 (amNG71, supplied by W. B. Wood) was examined. Both wild-type and doubly mutant recombinants were found. The cross was repeated with the mutant markers in coupling. The marker amH39 (gene 30) was also included in both crosses in the hope of ordering the mutations by three-point tests. Parallel crosses were made with go590-1 replaced by amN54. The results of the four crosses are summarised in Table 1. If go590-1 is due to a multisite mutation it might be anticipated that recombination between it and amNG71 is less than between am-N54 and amNG71 because the effect of a multisite mutation might reduce recombination beyond amN54 in either direction. The results show no evidence for that hypothesis. We also note that the data suggest that the order of markers is that used in Table 1, namely amH39-amN54 (or go590-1)-amNG71. High negative interference reduced the effectiveness of the threepoint test here as in other cases of close linkage<sup>11</sup> so that the ordering of the markers in these crosses is less than completely

Four T4 mutants of independent origin able to grow on hd590 were isolated by Barbara North and Gary Thorgaard, who permitted us to comment here on their results. Each of these strains simultaneously acquired the ability to multiply also on the bacterial mutant hdF isolated by Revel<sup>13</sup>. All of these strains differ from go590-1 which is unable to make plaques on hdF. H. R. Revel (personal communication) has shown that her T4goF

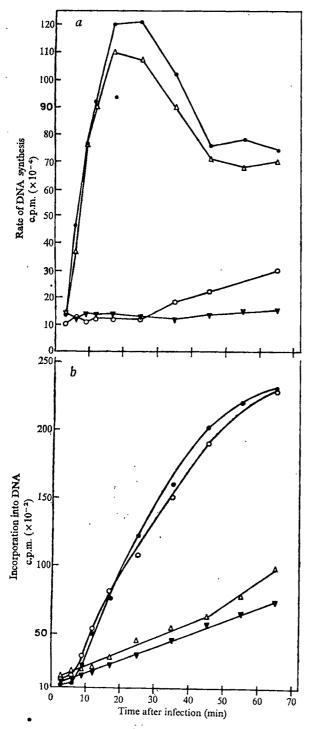

Fig. 4 Synthesis of DNA after T4 infection of hd590 and B011'. Bacteria were grown to 5 × 10<sup>8</sup> ml<sup>-1</sup> at 37° C in tryptone broth which contained 100 μg ml<sup>-1</sup> deoxyadenosine and 0.5 μg ml<sup>-1</sup> thymidine. The cells were then infected with the appropriate T4 particles (MOI = 5) and 7 min later they were superinfected (MOI = 5) with the same type of phage. a, To measure rates of DNA synthesis, at various times after infection, 1 ml samples were removed from the culture; they were added to 10 μCi <sup>3</sup>H-thymidine. Two minutes later ice-cold TCA plus thymidine was added to a concentration of 10% TCA, 50 μg ml<sup>-1</sup> thymidine. After 10 min the material insoluble in the cold, 10% TCA was collected on glass fibre filters which were washed twice with 5% TCA containing 25 μg ml<sup>-1</sup> thymidine and then twice with ethanol. The filters were dried and counted in a liquid scintillation counter. Δ, B011': T4+; ♠, B011': T4go590-1; ▼, hd590: T4+; ♠, hd590: T4+go590-1. b, To measure total TCA-precipitable DNA <sup>3</sup>H-thymidine (10 μCi ml<sup>-1</sup>) was added to the bacterial cultures at the time of infection. At various times thereafter 10 μl samples were placed on filters which were then immersed in ice-cold 10% TCA. The filters were then treated as described in (a). ♠, B011': T4+; ♠, B011': T4go590-1; ▼, hd590: T4+; ♠, hd590: T4+; ♠, hd590: T4+go590-1.

- 7

mutants map in the vicinity of gene 39. One of the new go590 mutants has been shown to map far from gene 31 and near gene 39, having yielded 4.4% recombinants with amS2 (gene 39). It seems clear that either a mutation in gene 31, a gene essential for capsid development, or a mutation in another region separated from gene 31 by one-fourth of the T4 chromosome, can compensate for the alteration of hd590 which prevents wildtype T4 from multiplying in it.

#### **Implications**

The data presented here describe a host defective bacterium, *E. coli hd5*90, in which the production of T4+ phages is blocked. Unlike other T4 *hd* bacteria that have been reported<sup>1-3,6,7</sup>, T4+infected *hd5*90 cells show: (1) an abnormally low rate of phage DNA synthesis, a rate which is constant throughout the latent

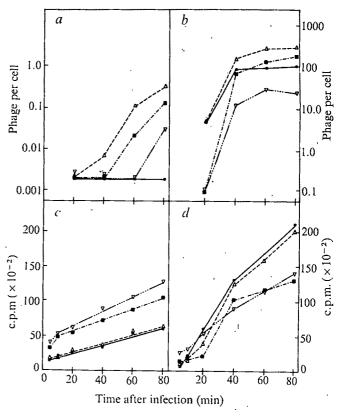

Fig. 5 Effect of EDTA on T4<sup>+</sup> production in hd590 and in B011'. Bacteria were grown to  $5 \times 10^8$  cells ml<sup>-1</sup> at 37° C in tryptone broth which contained 100 µg ml<sup>-1</sup> deoxyadenosine and 0.5 µg ml<sup>-1</sup> thymidine. EDTA was then added to the appropriate final concentration and the cells were infected with T4<sup>+</sup> particles (MOI = 3); 5 min later the cells were superinfected to inhibit lysis with additional phages (MOI=3). In experiments to measure phage production, anti T4 serum was added to the cultures 10 min after infection to inactivate unadsorbed T4 particles, and 5 min later the cultures were diluted  $10^3$ -fold to prevent inactivation of progeny phages. At various times thereafter, samples were withdrawn from the cultures, lysed with chloroform, and assayed for plaque-forming T4 particles. Experiments to measure DNA synthesis were performed as described in Fig. 4b. a, Phage production in hd590; b, phage production in B011'; c, DNA synthesis in hd590; d, DNA synthesis in B011'. , No EDTA;  $\triangle$ , 0.2 mM EDTA;  $\square$ , 1.0 mM EDTA;  $\triangledown$ , 5.0 mM EDTA.

period; (2) relatively small amounts or the absence of specific late T4 proteins; (3) empty heads, but no tails or tail fibres, in lysates. The absence of tails and tail fibres is probably due to the absence of the products of genes 7 and 34 in T4+-infected hd590 samples, gene products that are parts of the T4 baseplate and tail fibre, respectively. Two types of T4 mutants, one which appears to map near T4 gene 39 and one which appears to map

Crosses were made in *E. coli* CR63 following the methods outlined by Chase and Doermann<sup>11</sup>. The genotypes of individual progeny phages were identified as described by Doermann and Boehner<sup>12</sup>, but with the following technical modifications to accommodate peculiarities of specific mutants. The wild-type and mutant alleles of go590-1 were distinguished by replicating on to a test plate in which the 5ml soft-agar overlay contained  $2.5 \times 10^7$  wild-type T4 per ml. 0.4 ml of a 20:1 mixture (v/v) of aerated overnight broth cultures of hd590 and CR63/s, and streptomycin (hd590 is resistant to streptomycin, having been derived from the streptomycin-resistant strain 011'). To differentiate amH39 from its wild-type allele a streptomycinresistant mutant was isolated from the *E. coli* strain *lop8lig2* isolated by Gellert and Bullock<sup>14</sup> and supplied by Hillard Berger. The soft agar overlay of the replica plates contained, in addition to streptomycin,  $10^7$  amH39 phage per ml as well as 0.4 ml of a 59:1 mixture (v/v) of overnight cultures of lop8lig2/s and CR63/s. The amNG71 tests were made using streptomycin, a 20:1 mixture of B/s and Cr63/s, and  $2.5 \times 10^7$  amNG71 per ml soft agar. In the Table,  $am_1$ ,  $am_2$ , and  $am_3$ represent amH39, amN54, and amNG71 respectively. Asterisks mark the classes in each cross presumed to be double crossovers on which the order of the markers has been based. The parental classes are, of course, the most frequent pair.

in T4 gene 31, can overcome the hd590 block. T4 gene 39 seems to function to promote normal T4 DNA synthesis<sup>15</sup>; T4 gene 31 has been thought to function specifically in T4 head assembly. The 31 mutant, T4go590-1, is different from those other mutants in gene 31 which are able to produce phage in the hd cells which block T4 head morphogenesis<sup>1-3</sup>. This is the first report, to our knowledge, of a T4 gene 31 mutant which affects the synthesis of T4 DNA and late proteins.

Although we could not transfer the hd590 character into another cell, two lines of evidence suggest that the block in T4 production results from a single host cell mutation. First, mutant T4 phages, such as T4go590-1, which can overcome the hd590 block appear to be mutated in a single gene. Therefore, one specific phage alteration can affect T4 DNA synthesis, protein synthesis and head filling in hd590. Second, preliminary studies suggest that among bacterial revertants the various aspects of the hd590 character are lost jointly, as would be expected if the hd590 phenotype were due to a single mutation.

If the hd590 character results from a single alteration of the host cell, what is its molecular basis? The low rate of T4 DNA synthesis in hd590 cells does not seem to result from a failure to synthesise T4 DNA polymerase (gene 43 product<sup>16</sup>). In extracts of T4+-infected hd590 cells, we find normal levels of T4 polymerase activity in vitro (unpublished data of D.S., B. Fansler and L. D. S.). Furthermore, sedimentation profile analysis (unpublished data of McLaughlin and L. D. S.) indicates that the apparent low rate of DNA synthesis in T4+-infected hd590 cultures is not due to degradation of the T4 DNA.

In normal T4+ infection, late mRNA production is coupled with DNA synthesis<sup>17</sup>. Since T4 DNA synthesis is abnormal in hd590, the synthesis of late mRNA may also be abnormal, and, if so, may be responsible for the reduced synthesis of specific late T4 proteins in T4+-infected hd590 cells. Alternatively, the hd590 defect might specifically prevent assembly of tail fibres and baseplates, thereby leaving the products of genes 7 and 34 unassembled, and sensitive to proteolytic activities within the infected cell. It seems unlikely that the absence of various proteins from T4+-infected hd590 cells is simply due to an increased host cell protease activity, since T5 and T7 phages plate with normal efficiency on hd590.

Available evidence suggests that the altered host cell component in hd590 may be associated with its inner membrane. This suggestion is based on two observations. (1) Low concentrations of EDTA, which primarily seem to affect the bacterial membrane<sup>18</sup>, stimulate T4+ DNA synthesis and phage production in hd590. (2) A specific T4 mutant in gene 31, T4go590-1, can overcome the hd590 block in T4 production. T4 gene 31 product normally functions in the assembly of the T4 capsid, at the level of cell membrane interaction with T4 head proteins<sup>4,5</sup>. Thus, either EDTA or a specific mutant T4 gene 31 product, both of which may interact with the host cell inner membrane, can stimulate T4 DNA synthesis and phage production in E. coli hd590.

Georgopolous and Herskowitz<sup>18</sup> have described hd mutants called GroP- which affect  $\lambda$  DNA synthesis. Specific  $\lambda$  mutants in gene P can overcome the GroP-block, presumably by making an altered P product that can interact with the altered host cell component. The GroP- defect has been traced to an alteration of the DNA 'B' gene of E. coli<sup>19</sup>. The low level of T4 DNA synthesis in hd590 cells might also be due to an alteration of the bacterial DNA synthesis machinery. This suggestion would imply a greater dependence of T4 on the E. coli DNA replication system than has heretofore been assumed, since T4, in contrast to \(\lambda\), codes for more than 20 phage-induced enzymes of DNA metabolism<sup>20</sup>—including DNA polymerase<sup>16</sup>, polynucleotide ligase21, polynucleotide kinase22 and various deoxyribonucleases23.

This work was supported by grants from the United States National Science Foundation (to L. D. S.) and the National Institutes of Health to The Institute for Cancer Research, and by an appropriation from the Commonwealth of Pennsylvania to The Institute for Cancer Research. We also thank Miss Linde Boehner for performing the genetic mapping experiments. Those experiments were supported by a grant from the National Institute of General Medical Sciences to A.H.D.

# Evolution of C-type viral genes: inheritance of exogenously acquired viral genes

Raoul E. Benveniste & George J. Todaro

Viral Leukemia and Lymphoma Branch, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20014

Genes related to the nucleic acid of an endogenous domestic cat C-type virus (RD114) are found in the cellular DNA of anthropoid primates while many members of the cat family Felidae lack these sequences. Endogenous viruses from primates are thus concluded to have infected and become part of the germ line of an evolutionarily distant group, the ancestors of the domestic cat.

We have evidence that C-type viruses have in the past been transferred between vertebrate species that are only remotely related phylogenetically. Our data suggest that viral genes from one group of animals can give rise to infectious particles that not only can integrate into the DNA of another species, but can also be incorporated into the germ line and be transmitted as cellular genes. We have found that the RD114/CCC group<sup>1-3</sup> of endogenous feline viruses originated from a primate C-type virus horizontally transmitted to some species of *Felis* relatively recently in feline evolution.

The chromosomal DNA of various mammalian species contains multiple copies of nucleic acid sequences that can code for the production of endogenous C-type viral particles<sup>4</sup>. With <sup>3</sup>H-DNA transcripts prepared from the endogenous baboon C-type viruses<sup>5,6</sup>, partially homologous sequences have been detected in the cellular DNA of Old World monkeys, apes and man<sup>7,8</sup>. These virogenes have evolved for at least 30 Myr among the anthropoid primates in a fashion that correlates closely with the taxonomic relatedness of the species8. Domestic cat DNA contains C-type virogenes9-12 which can give rise to RD114/CCC viruses<sup>2,3</sup>. By several criteria, including nucleic acid sequence homology<sup>5,7</sup> and antigenicity of the polymerase and the p30 protein<sup>6,13,14</sup>, these viruses are related to, but distinct from, the baboon viruses. The unexpected relatedness of the endogenous cat and the endogenous baboon viruses suggested that they had a common origin.

#### RD114-related sequences in cats and primates

The origin of the RD114/CCC cat viruses can be clarified by examining the cellular DNAs from other members of the Felidae, which consist of 36 species belonging to six genera. The use of labelled unique sequence (non-repetitive) cellular DNA to compare the extent of nucleotide sequence divergence among species has shown that the cellular DNAs of the species examined have a nucleic acid sequence homology consistent with classical phylogeny<sup>15</sup>. Hybridisation of labelled uniquesequence domestic cat DNA to the DNA of other Felidae (Fig. 1b) showed that they are all closely related. The DNA of another carnivore (dog) contains much less sequence homology to domestic cat cellular DNA. All modern carnivores are believed to have had a common ancestor approximately 35 Myr ago; the close relationship observed between the DNA of all members of the Felidae indicates that they represent a more recent radiation (<15 Myr ago). The cellular DNA of the cats examined thus contains nucleic acid sequences closely related to each other, as are those of the Old World monkey subfamily Cercopithecinaes. The Felidae and the Cercopithecinae, however, lack detectable reciprocal DNA sequence homology.

Hybridisation of cat cellular DNAs to a <sup>3</sup>H-DNA transcript prepared from RD114 virus (Fig. 1a) showed that homology was greatest with the domestic cat (Felis catus) DNA; at the maximal extent of the reaction, approximately 80% of <sup>3</sup>H-DNA was resistant to digestion with the single-strand specific nuclease, S<sub>1</sub>. The cell DNA from three other species of cats, European wildcat (F. sylvestris), sand cat (F. margarita) and jungle cat (F. chaus), also contained nucleic acid sequences homologous to the RD114 <sup>3</sup>H-DNA probe. Under our hybridisation conditions, however, no other species of Felis or any other feline genus had base sequences related to RD114. In contrast, the DNA of all primate species whose unique sequence cellular

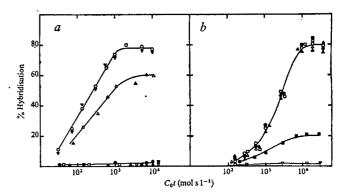

Fig. 1 Hybridisation of RD114 C-type viral ³H-DNA probe and domestic cat unique sequence cellular ³H-DNA to feline cellular DNAs. The ³H-thymidine-labelled DNA probes were synthesised from detergent-disrupted C-type virus in the presence of actinomycin D as described¹³. The specific activity of the ³H-DNA was 1.8 × 10° c.p.m. µg⁻¹. The ³H-DNA probes contained 63–72% of their respective 70S viral RNA sequences at a ³H-DNA: ³²P-viral RNA molar ratio of 1.5 (ref. 7), indicating that they contain most of the sequences present in viral RNA and that these sequences are in proportions similar to their content in 70S RNA. Cellular DNA was extracted from tissues and cell lines as described². All DNAs were sonically treated so as to yield a mean size of 6-85 (the size of the ³H-DNA probes) as determined by centrifugation on alkaline sucrose gradients². DNA: DNA hybridisations were incubated at 65° C in reaction mixtures containing 0.01 M Tris, pH 7.4, 0.75 M NaCl, 2 × 10⁻³ M EDTA, 0.05% SDS, 10,000 to 20,000 c.p.m. of ³H-DNA and 1-3 mg of cellular DNA per ml. Hybridisations were started by heating the mixtures to 98° C for 10 min, cooling on ice to 4° C and incubating at 65° C. At various times (from 15 min to 96 h), 0.05 ml portions were removed and frozen at −80° C until digested with the single-strand-specific nuclease, S₁, as described¹³. C₀t values (C₀ is the concentration of cellular DNA in mol 1⁻¹, and t is the time in seconds) were calculated as suggested by Britten and Kohne²o as (A₂₀o ml⁻¹) / 2 × h, and corrected to a monovalent cation concentration of 0.18 M²¹. a, Annealing of ³H-DNA probe prepared from RD114 grown in RD cells¹ to DNA extracted from: (△) ionspleen; (♠) leopard cat spleen; (□) tiger liver; (△) lion spleen; (♠) dog liver; (√) human spleen. b, Annealing of unique sequence domestic cat cellular ³H-DNA to the cellular DNA of various cats. The DNA of a domestic cat cell line was labelled with ³H-thymidine and extracted². Unique sequence cellular DNA was isolated by removing the highly reiterated se

DNA is homologous (or nearly so) to baboon cellular DNA hybridised extensively to the baboon C-type virus probe<sup>7,8</sup>.

The thermal stability of nucleic acid hybrids is an index of base-pair mismatching between the strands of a double-strand DNA molecule. Mismatching yields hybrids that melt at a lower temperature; the overall effect of mismatched base-pairs on the thermal stability is approximately 1° C for 1% altered base-pairs<sup>16</sup>. Thermal stability data obtained with 13 species representing six feline genera by using either labelled nonrepeated domestic cat cellular DNA or 3H-RD114 viral DNA as a probe are shown in Table 1. Although the overall uniquesequence cellular DNAs of all the cat species were highly homologous (the largest difference in thermal stability is less than 2° C), only four species of Felis contained RD114-related sequences. There were no sequences related to RD114 3H-DNA in two carnivore species (mink and dog) or in mouse or cow cell DNA. Nucleic acid sequences related to RD114 were found in six species of Old World monkeys. Among the apes,

sequences related to RD114 or CCC <sup>3</sup>H-DNA probes can be detected readily in chimpanzee and gorilla cellular DNA. For reasons not yet clear, greater homology has been observed consistently with these two apes as compared with gibbon and human DNA. Sequences related to the baboon C-type virus, while found in all apes, are also detected more readily in chimpanzee and gorilla DNA<sup>8</sup>. Hyman DNA has been examined for RD114-related nucleic acid sequences with negative results<sup>9-12</sup>. The lack of detectable sequence homology of human DNA with RD114 is not due to an absence of RD114-related information. In support of this conclusion, p30 protein partially related to RD114 p30 can be found in tissues of humans<sup>17</sup>, as well as baboons<sup>13</sup> and other Old World monkevs<sup>18</sup>.

Melting curves obtained with a single-stranded <sup>3</sup>H-DNA transcript of RD114 RNA hybridised to the DNA of domestic and jungle cat and to the DNA of Old World monkeys are shown in Fig. 2a. The RD114-related sequences in these

<sup>\*</sup> Cellular DNA was extracted from various tissues of the species listed.

† Since its domestication this cat has travelled with man all over the world. All breeds of the domestic cat (for example, Burmese, Siamese and Abyssinian) belong to the same species.

§ A  $^{3}$ H-DNA probe prepared from RD114 virus grown in a human cell line was used for the hybridisations to feline DNA, and a  $^{3}$ H-DNA probe prepared from CCC virus grown in a canine thymus cell line (FCf2Th) for the hybridisations to primate DNA. The  $T_{\rm m}$  of the homologous RD114: domestic cat DNA hybrid was 88.5° C.

NT, not tested.

<sup>† &</sup>lt;sup>3</sup>H-thymidine-labelled unique sequence domestic cat cellular DNA was hybridised to the cellular DNA of the various species as described in Fig. 1. The % hybrid is the saturating normalised value obtained after digestion of the hybrids with  $S_1$  nuclease. The actual final extent of domestic cat cell DNA hybridisation to the cellular <sup>3</sup>H-DNA probe was 73%. The temperature at which 50% of the hybrids are dissociated  $(T_m)$  was 85° C for the homologous domestic cat: domestic cat hybrid; the  $\Delta T_m$  is the difference in  $T_m$  between the other DNA hybrids and the  $T_m$  of the homologous hybrid. The  $T_m$  of hybrids that hybridise less than 3% cannot be determined because of insufficient homology. § A <sup>3</sup>H-DNA probe prepared from RD114 virus grown in a human cell line was used for the hybridisations to feline DNA, and a <sup>3</sup>H-DNA

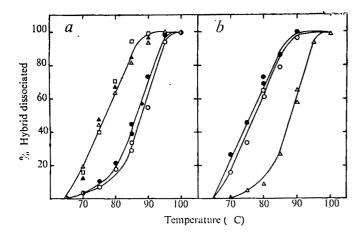

Fig. 2 Thermal stability of hybrids formed between baboon viral 3H-DNA and RD114 3H-DNA and various feline and primate cellular DNAs. a, An RD114 3H-DNA probe was hybridised to DNA extracted from: (O) domestic cat liver; (●) jungle cat spleen; (△) baboon lung; (▲) patas liver; (□) rhesus liver. b, A baboon C-type <sup>3</sup>H-DNA probe was hybridised to DNA extracted from: (△) baboon lung; (○) domestic cat liver; (●) jungle cat spleen. After hybridising to a Cot of 104, aliquots (containing 400 to 700 c.p.m.) were heated for 5 min in 0.75 M NaCl at the indicated temperatures. The amount of hybrid remaining was determined with the singlestrand-specific nuclease, S1.

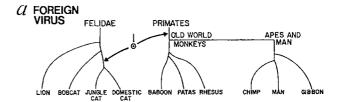

primates melt at approximately 11° C lower than the homologous hybrid. The lower thermal melting points obtained with the Old World monkey DNAs indicate that the partial homology detected is not the result of a strict preservation of discrete continuous segments of the viral genomes in these species, but rather of a more general base-pair substitution throughout the genome. Figure 2b shows the reciprocal experiment: the melting curves obtained when a single-stranded 3H-DNA transcript of baboon C-type viral RNA was hybridised to the DNA of baboon and domestic and jungle cat. Again, baboon type C related sequences in the cellular DNA of the two cats melt at about 11° C lower than the homologous hybrid.

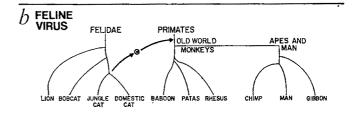

#### Models for viral transmission among species

When the virogenes of two species are more closely related to each other than are the cellular genes, one must suspect horizontal transmission and subsequent perpetuation of the viral genes through the germ line. Figure 3 shows models which could account for the data. A virus of unknown origin infects the ancestors of certain cats and primates in model a. In model b, a virus ancestral to the four species of cats described above infects an ancestor of the Old World monkeys and apes. In model c, the converse occurs: an endogenous primate virus infects a recent ancestor of the domestic cat. If RD114 were an endogenous Felidae virus, there should be sequences related to it in the cellular DNA of all Felidae. Since RD114-related nucleic acid sequences can be found in all Old World monkey and ape tissues but in just four closely-related species of Felidae, we conclude that RD114 is a primate C-type virus, as shown in model c. The greater homology to RD114 nucleic acid sequences in Old World monkey cell DNA than in ape DNAs (Table 1) shows that the transmission occurred after the Old World monkeys and the apes diverged (arrow II or III). Since all the Old World monkey DNAs show comparable levels of homology to RD114, model cII is most likely.

The cats of the genus Felis that contain DNA sequences related to RD114 are from the Mediterranean basin (Table 1) while those from south-east Asia and the New World lack these sequences. The larger African cats (leopard and lion) also do not contain RD114 sequences in their cellular DNA. Therefore, the successful transmission of gene sequences was subsequent to the major radiation of Felidae and limited to one geographic

C-type viruses have thus under natural conditions transferred genetic information between species that are only remotely related phylogenetically. We have shown here that viral genes from one group of animals can give rise to infectious particles that not only can integrate into the DNA of animals of another species, but can also be incorporated into the germ line. There may well be other examples among C-type viruses of germ line inheritance of exogenously acquired viral genes.

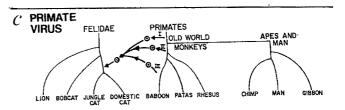

Fig. 3 Schematic representation of models which could account for the presence of related virogene information in primates and domestic cats. a, Common foreign virus infection of ancestors of both Old World monkeys and domestic cats. b, Infection of the ancestors of Old World monkeys and apes by a cat virus. c, Infection of the ancestors of domestic cats and jungle cats by a primate virus. Three possible times for the infection are shown and discussed in the text: (I) before the Old World monkeys and apes diverged (> 30 Myr ago); (II) before the Old World monkeys diverged (> 5-10 Myr ago); (III) recently by a baboon C-type virus (<10 Myr ago).

# letters to nature

# Equivalence principle: 60 years of a misuse?

Ever since Einstein introduced the equivalence principle and used it, in conjunction with the Doppler effect, to derive the gravitational redshift of spectral lines1, this argument has been an ingredient of many<sup>2-6</sup> (though not all<sup>7-11</sup>) expositions of relativity theory. We show here that on this point Einstein was in error, although the result found is correct (to first

Briefly, the usual reasoning runs that a source S emits a photon of frequency  $v_s$  towards a detector D when both are relatively at rest at distance I apart. At the same instant the detector commences a relative motion with constant acceleration g relative to, and away from, S. D receives the photon at time  $t \sim l/c$  when it has acquired a relative velocity  $v = gt \sim gl/c$ . The observed frequency  $\nu_{\scriptscriptstyle D}$  at the detector is therefore subject to a Doppler redshift and is given to first order by

$$v_{\rm D} = (1 - v/c)v_{\rm S} = (1 - gl/c^2)v_{\rm S}$$
 (1)

The frequency of a photon is therefore redshifted as it ascends a gravitational field if, by the equivalence principle, the acceleration is replaced by a gravitational field g acting in the opposite direction, that is from D to S. Previously synchronised clocks therefore run slower the deeper they are placed in a gravitational field and hence space-time acquires a non-Minkowskian metric.

This reasoning uses the first order longitudinal Doppler effect which is a part also of Newtonian physics. Since 'fictitious' forces, and the equivalence principle, can be considered to be also part of Newtonian physics the reasoning just offered leads to a gravitational redshift and a timetransformation in Newtonian physics. This is an absurd conclusion, since Newtonian physics operates with an absolute time.

The cause of the trouble lies in the application of the equivalence principle. All physical measurements must be imagined to be made with respect to the accelerated frame, but the Doppler formulae involve two different frames (normally both inertial, although generalisations are possible). We have gone back to fundamentals and considered pairs of signals (which is how the Doppler formulae are deduced) and obtained an argument (too lengthy to be set out here) which satisfies the constraint that the gravitational redshift is zero in Newtonian physics, but satisfies equation (1) to first order if special relativity is used and g is interpreted to be a gravitational acceleration. Our argument for Newtonian physics uses a particle picture of light and attributes different velocities to the two signals.

A manuscript giving details will be submitted shortly. Here we merely observe that as a result of what has been said, it is not to be expected that the incorporation in the usual Doppler shift argument of a more accurate Doppler shift expression can be of relevance to the gravitational redshift, as recently proposed12. This argument leads to a relationship between measurements in the inertial frame and a non-inertial frame, and is thus not suitable for a discussion of the gravitational redshift. What is achieved in ref. 12 is the following: If in the argument at the beginning of this letter D is undergoing a constant proper acceleration g away from S, then equation (1) holds exactly. This is a correct result for Doppler shifts arising in hyperbolic motion.

We note, furthermore, that in a gravitational redshift formula which is exact within the framework of special relativity and the equivalence principle (that is, for flat space-times), the way in which lengths are imagined to be measured affects the result. If *l* is the proper or ruler distance between the stationary source and detector in a gravitational field g(x), which can be a function of distance and which is parallel to SD, then we find that equation (1) is indeed exact in the above sense, g being the gravitational acceleration at D. If, however, either coordinate distance or radar distance are used we find that equation (1) holds only to first order.

These results are clearly relevant to ref. 12 and any discussion it may precipitate. N.T.B. thanks the Science Research Council for a research studentship.

### Gravitational searchlight and its astrophysical applications

We wish to point out an interesting effect associated with light emitted in the forward direction by a source circulating in an equatorial plane around a highly collapsed object or a black hole of mass M. The essential feature of the emission is that provided the radius a of the orbit in Schwarzschild's coordinates exceeds  $3GM/c^2$ , the light emitted is blueshifted when received by a distant observer. More specifically, if  $v_0$  is the frequency of light at emission and v the frequency at reception at a radial coordinate  $R \gg R_s = 2GM/c^2$ , we have

$$\frac{v}{v_0} = \frac{\sqrt{[(2-3\xi)(1-\xi)]}}{\sqrt{[2(1-\xi)]} - \sqrt{\xi}}$$
(1)

where

$$\xi = R_s/a \tag{2}$$

While  $v > v_0$  for all values of  $\xi < 2/3$ , it can be shown easily that as  $\xi \rightarrow 2/3$ , the blueshift diverges. Writing  $\xi = (2/3)(1-\epsilon)$ ,

$$v \simeq (2/3) v_0 \varepsilon^{-1/2} \text{ as } \varepsilon \rightarrow 0$$
 (3)

Thus very high blueshifts are obtained as the orbit of the particle tends to the so called unstable circular orbit. Qualitatively, we can understand the result in terms of the competition between the Doppler blueshift of forward light emission and the gravitational redshift due to the central mass. The former increases much more rapidly than the latter as  $\epsilon \rightarrow 0$ . We are interested here with orbits with very small  $\varepsilon$ , that is, orbits close to the unstable circular orbit.

The behaviour of matter revolving very close to such an orbit has been considered by several authors<sup>1-3</sup>. For example, an electron moving in a circular orbit can emit synchrotrontype radiation. It is also possible for gravitational radiation to be emitted by revolving matter. Such effects, however, have turned out to be very small even in the limiting case of  $\varepsilon \rightarrow 0$ . Here we suggest an alternative situation where the above mentioned result can play a significant part.

Before coming to the astrophysical setting consider what happens when we have matter moving in a thin ring round an object with mass M, with say  $\varepsilon_1 \le \varepsilon \le \varepsilon_2 \le 1$ . Suppose matter in this region has uniform distribution and is emitting light in a band of frequencies peaked round  $v_0$ , say. Then purely geometrical considerations and equation (3) lead to a reception spectrum at R of the form

$$F(v) = A(v_0) v^{-1}, v \ge v_0$$
 (4)

The function  $A(v_0)$  depends on the dimensions of the object and the emissivity of matter under consideration. The derivation of equations (3) and (4) is somewhat involved and will be published elsewhere, but the  $v^{-1}$  dependence of the spectrum purely on geometrical ground is noteworthy.

Turning now to the astrophysical considerations, it is well known that a highly collapsed object or a black hole tends to accrete matter. In general the infalling matter has some angular momentum so that it does not fall in radially. Instead, one can imagine matter making revolutions round the object several times before falling in. The unstable circular orbit is likely to play an interesting part in this process. The infalling matter goes round in orbits with small  $\varepsilon$  several times before getting sucked in or thrown out again<sup>1</sup>. So we may consider the thin ring discussed above as made up of transient matter.

The v-1 spectrum is common to many extragalactic sources of radiation. We have considered the continuum emission of QSOs whose spectrum can be approximated this way<sup>4</sup>. By considering thermal emission from hot gas in a narrow range of frequencies around  $v_0 \sim 3 \times 10^{14}$  Hz and taking the emissivity<sup>5</sup> as  $\sim 4.4 \times 10^{-24} n_e^2$  erg cm<sup>-3</sup> s<sup>-1</sup>, with  $n_e$  the electron density in cm<sup>-3</sup> we find that in order to explain the observations of a QSO like 3C273 in the optical and ultraviolet region on the basis of equation (4) we need a mass-distance relationship of the form

$$M/M_{\odot} \simeq 1.7 \times 10^{15} (R_{\rm mpc}/n_{\rm e})^{2/3}$$
 (5)

Here  $R_{mpc}$  is R expressed in Mpc. In a 'local hypothesis',  $R_{\rm mpc}$  may not exceed ~100 while  $n_{\rm e}$  can be taken as high as  $\sim 10^9$  to give a mass M of the order of that of a galaxy. Provided thermal emission is confined to relatively narrow band of frequencies at the source, the resulting spectrum at a large distance will show a  $v^{-1}$  dependence.

The light emitted in the forward direction makes several rounds of the object before reaching the distant receiver. As  $\varepsilon \rightarrow 0$ , the angle through which the light has turned can be shown to be

$$\varphi \sim \ln[(24 - 12\sqrt{3})/\epsilon]$$
 (6)

Thus for  $\varepsilon \sim 10^{-10}$  the light will go round nearly four times. J. V. N. thanks the Jawaharlal Nehru Fund for the award

# Solar energetic particle event with $^{3}\text{He}/^{4}\text{He}>1$

OBSERVATIONS of  $\gamma$  rays and the short lived isotope <sup>3</sup>H provide evidence for the occurrence of nuclear reactions by high energy particles accelerated in solar flares1,2. Stable isotopes such as <sup>2</sup>H and <sup>3</sup>He should also be produced in these reactions. Solar <sup>3</sup>He particles were first detected by Hsieh and Simpson<sup>3</sup>. In the energy range 10 to 100 MeV per nucleon they obtained  $^3\mathrm{He}/^4\mathrm{He} = (2.1 \pm 0.4) \times 10^{-2}$  by summing over seven solar particle events. Garrard et al.4 and Anglin et al.5 have reported that 3He/4He was highly variable from event to event. (Table 1). In the '3He-rich events', 2H and 3H were not detected and the resulting upper limits were much less than expected from the theory of nuclear reactions6. These events were small, and the

Chromosphere $\leq (1.0 \pm 0.5) \times 10^{-2} \text{ (ref. 9)}$ Solar wind $4 \times 10^{-4} \text{ (ref. 11)}$ $\leq 4 \times 10^{-4} \text{ (ref. 10)}$	~ 1.4 × 10 <sup>-4</sup> , September 25, 1969 (Dietrich and Simpson, unpublished) Chromosphere and prominences ~ 0.06 (ref. 12) Solar wind ~ 0.045 (ref. 17)				

number of  ${}^{3}$ He particles observed was low ( $\sim$  70). This anomalous production of  ${}^{3}$ He should provide new insight into the acceleration and confinement process of energetic particles in solar flares.

Using the Goddard cosmic-ray telescopes of OGO-V (ref. 7) we detected an unusual solar event on May 28, 1969. The flare associated with the event occurred at 1248 local time and had importance 1B. The solar coordinates of the event are 10°N and 56°W with the associated McMath plage region 10109. About 600 ³He nuclei were detected in this event and  $^{3}\text{He}/^{4}\text{He} = 1.52 \pm 0.1$  in the energy range 4 to 80 meV per nucleon. This is the highest ratio reported so far for any solar event.

. Fig. 1 Mass histogram for He nuclei observed in the solar particle events on May 28 and November 2, 1969. Note dominance of <sup>3</sup>He in the May 28 event. The <sup>3</sup>He/<sup>4</sup>He ratio for the November 2 event is 0.08, in agreement with that reported by Dietrich<sup>8</sup>.

—, May 28 event; \*, November 2 event.

In Fig. 1 we give the mass histograms for He nuclei. The dotted curve represents the mass distribution (normalised at the peak of <sup>4</sup>He distribution) for another event on November 2, 1969. For this event we get <sup>3</sup>He/<sup>4</sup>He = 0.08, in excellent agreement with Dietrich<sup>8</sup>.

The ratio of hydrogen to helium for the event on May 28 is also highly unusual with  $^1H/(^3He+^4He)=1.00\pm0.05$  (Table 1).

The energy spectra of three components were all consistent with power laws in kinetic energy per nucleon. The exponents for  $^{1}$ H,  $^{3}$ He and  $^{4}$ He were  $-4.29 \pm 0.10$ ,  $-4.16 \pm 0.10$  and  $-4.04 \pm 0.11$ , respectively

The observed upper limit to  ${}^{3}\text{He}/{}^{4}\text{He}$  in the solar chromosphere was  $(1 \pm 0.5) \times 10^{-2}$  (ref. 9). In the solar wind  ${}^{3}\text{He}/{}^{4}\text{He} \sim 10^{-4}$  (refs 10 and 11). The solar particles have higher relative abundance of  ${}^{3}\text{He}$  in comparison with the solar chromosphere. The  ${}^{4}\text{He}/{}^{1}\text{H}$  ratio is also large compared to the observations on solar prominences 12. In Table 1, the isotopic abundances of He as obtained from several related studies are shown for comparison.

Ramaty and Kozlovsky<sup>13</sup> have proposed a theory dealing with the production of <sup>2</sup>H, <sup>3</sup>H and <sup>3</sup>He in solar events. They have taken into account effects of kinematics of the reactions and the possible anisotropy of solar beams to explain the anomalously small <sup>2</sup>H and <sup>3</sup>H abundances compared to <sup>3</sup>He. They find that for energetic protons and 4He nuclei incident on the solar atmosphere, 3He will be preferentially emitted in the direction opposite to that of the incident particle whereas <sup>2</sup>H and <sup>3</sup>H will tend to have the same direction. For the giant flare in August, 1972 (ref. 14), they arrive at about 2 gm cm<sup>-2</sup> to account for  $^{3}\text{He}/^{4}\text{He}$  of  $\sim 0.02$  observed in the event. They also relate the y-ray intensities observed by Chupp et al.7 with the energetic protons observed in the event. The large production of 3He according to Ramaty and Kozlovsky, occurs only at low energies (about 0.1 meV per nucleon) and so some post acceleration is necessary to account for the observed particles.

Using the same model to explain the very high 3He/4He ratio in the May 28 event requires the passage through 2.3 nucleon mean free paths or some 170 g cm<sup>-2</sup> of material for protons. This further requires that the ionisation energy loss be balanced by continuous acceleration which means that a 50 MeV per nucleon He nucleus would have to receive a total energy of ~ 12 GeV. This seems highly implausible. One possible clue may be provided by the simultaneous observation of the solar X rays and electrons. Here it is found that only  $10^{-2}$  to 10<sup>-3</sup> of the electrons escape with a large fraction incident on the lower corona which produces the X-ray emission. A similar effect may be occurring with the nuclear component though the rigidities of the nuclear particles are larger by factors > 10<sup>2</sup>. The other secondary products <sup>2</sup>H and <sup>3</sup>H are not seen in this event. Assuming that one nucleus of <sup>2</sup>H (or <sup>3</sup>H) was seen during the event, the upper limit for <sup>2</sup>H/<sup>3</sup>He (or <sup>3</sup>H/<sup>3</sup>He)

is  $\sim 1/600$ . Simultaneous  $\gamma$ -ray observations would be of great value in identifying the type of process and the time scale on which it operates. These were not available for this event. It is also possible that the solar material involved in these flares has an anomalous composition to start with.

## Formaldehyde polymers in interstellar space

THE precise composition of interstellar dust is as yet unknown. Recent studies of the wavelength dependence of extinction and polarisation favour a composite model of three components: (1) elongated dielectric particles of radii  $\sim 10^{-5}$  cm, which would explain the data in the 1-0.3 µm spectral region; (2) almost spherical graphite particles of radii  $\lesssim 2 \times 10^{-6}$  cm, which would explain the near and middle ultraviolet data in 0.3  $\gtrsim \lambda \gtrsim$ 0.2 µm; and (3) small dielectric particles which contribute mainly to extinction and albedo at wavelengths,  $\lambda \leq 0.2 \,\mu\text{m}$ .

There is considerable evidence to support the view that silicate grains exist in circumstellar envelopes around certain cool stars1. An emission feature in the 8-12 µm waveband occurring in the spectra of many cool Mira-type stars has been identified with particles of a mineral-like composition. It is also widely believed that silicate dust is responsible for a major part of the observed interstellar extinction and polarisation at visual wavelengths, in other words, that silicates make up component (1) above. The evidence for this is not convincing and several strong counter indications already exist. Applications of the Kramers-Kronig relationship to the observed interstellar extinction curve suggest that greater relative abundances

of Mg, Si to H than are consistent with cosmic abundance ratios are necessary to explain the observed extinction2.3. This discrepancy could be as much as a factor 10. It seems therefore, that the only elements present in sufficient quantity in the interstellar medium to contribute to the observed visual extinction coefficient,  $\kappa_{\nu} \sim 2$  mag kpc<sup>-1</sup>, are C,O and N. The possibility of O in the form of H<sub>2</sub>O ice has been discussed for many years, although a 3.1 µm ice band was not detected in the spectra of several moderately reddened stars4,5.

I have argued (N.C.W., unpublished) that formaldehyde molecules which have been detected in over a hundred interstellar clouds could condense on silicate grains. Condensation of  $H_2CO$  on silicate grains with temperatures  $\lesssim 20$  K is attended by polymerisation into chains

resulting in the formation of a crystalline polymer known as polyoxymethylene (POM). The constituent elements of this material are sufficiently abundant to provide the main contribution to the mass density of interstellar dust. These particles would grow as long whiskers under interstellar conditions and possess the required dielectric properties to account for component (1) in the composite grain model. In common with many other polymers, POM is moderately refractory with a melting temperature in the range 450-500 K. Such grains could survive in H II regions and radiate at temperatures  $T_{\rm g}$ ≤ 500 K thus accounting for many galactic infrared sources.

The optical refractive index of epoxy formaldehyde resin, which is likely to be similar to that of POM, is n = 1.58 (ref. 6). A cylindrical particle of radius close to  $1.5 \times 10^{-5}$  cm, with this value of n, possesses extinction and polarisation properties which are consistent with interstellar data7.

The strongest evidence adduced in support of the view that silicate grains are mainly responsible for the general interstellar extinction is the appearance of an 8-12 µm emission feature in the infrared spectrum of the Trapezium nebula, as well as a similar extinction feature in the spectrum of the BN star in the Orion nebula<sup>1,8,8</sup>. Most other 10 µm features observed in stars are confined to strictly circumstellar grains and do not necessarily relate to the behaviour of interstellar grains.

By a remarkable coincidence, POM polymers also exhibit strong optical activity in the 8-12 µm waveband. Figure 1 shows the absorption spectrum of POM films studied by Tadokoro et al<sup>10</sup>, for polarised light. Although this feature is comprised of two main bands, as in the case of silicates, a distribution function in average chain length will mask much of the fine structure, as the precise positions of individual bands depend on this parameter in the crystalline powder.

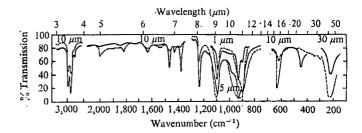

Fig. 1 Infrared transmission spectra for polarised light of POM-films of several thicknesses (1, 5, 10 and 30  $\mu$ m) for the various wavelength intervals as indicated in the insets. The solid curve refers to light with electric vector perpendicular to crystal axes; dashed curves for electric vector parallel to the crystal axes, (Differing thicknesses of film, 1, 5, 10 and 30  $\mu$ m, are used over various wavelength intervals. When this is noted, the 8-12  $\mu$ m bands are considerably stronger than others indicated in these data.)

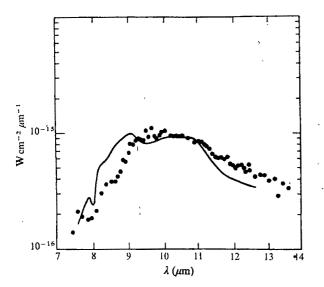

Fig. 2 The infrared emission (ω) from the Trapezium nebula compared with the theoretical flux from 445 K POM polymer grains (solid curve).

The average mass extinction coefficient at the centre of this band, estimated from the data of Tadokuro et al.10, is

$$\kappa_{10\mu m} \simeq 1.4 \times 10^3 \text{ cm}^2 \text{ g}^{-1}$$
 (1)

assuming a specific gravity s = 1.4 for POM. At the visual wavelength,  $\lambda_{\nu} = 5,470 \text{ Å}$ , the mass extinction coefficient for POM grains of radii,  $a = 1.5 \times 10^{-5}$  cm, is

$$\kappa_{\nu} \simeq (3Q_{\rm ext}/4as) \simeq 7.1 \times 10^4 \,\rm cm^2 \, g^{-1}$$
 (2)

Equations (1) and (2) give  $\kappa_{\nu}/\kappa_{10\mu m} \simeq 51$ . The corresponding ratio inferred from the astronomical data for extinction in the BN star is very similar  $(\kappa_{\nu}/\kappa_{10\mu\,\mathrm{m}})_{\mathrm{BN}} \simeq 50$  (ref. 1). Figure 1 shows that interstellar POM grains could give rise to somewhat weaker, yet probably detectable, features at  $\lambda \simeq 3 \,\mu m$  and  $\lambda \simeq 16-23 \,\mu m$ . The latter feature imparts a further ambiguity to the identification of silicate grains, whilst the former may be confused with the 3.1 µm band of H<sub>2</sub>O ice.

Absorbance data for heated POM films10 may be used to compute an approximate emission spectrum of small POM grains. The absorption efficiency of small particles, irrespective of shape, is proportional to the absorbance  $\gamma_{abs}$ , provided the refractive index n is close to 1 and the absorptive index kremains small throughout the band. Assuming these conditions to be fulfilled the emission spectrum of POM grains may be calculated by

$$F_{\lambda} \propto \gamma_{abs} B_{\lambda}(T_{g})$$

where  $B_{\lambda}(T_{\rm g})$  is the Planck function,  $T_{\rm g}$  is the grain temperature. The emission spectrum of the Trapezium nebula is shown in Fig. 2 together with a normalised emission spectrum for POM grains heated to 445 K. The agreement is as good as, if not better than, for any silicate model. POM grains are thus able to explain all available interstellar extinction and emission data.

In view of the spectral identifications presented here POM grains must clearly be regarded as a strong candidate for the main component of interstellar dust. Such grains could contribute a significantly higher mass density than silicate grains. More detailed measurements of the complex refractive index of POM as a function of wavelength and of temperature are required before further comparisons with astronomical data can be made.

Our provisional conclusion is that interstellar grains consist of a mixture of small graphite particles and silicate particles coated with POM mantles. The graphite and silicate particles

are ejected from cool giant stars; silicate grains have low enough temperatures under interstellar conditions to accrete POM polymer mantles.

I thank Professor J. C. D. Brand for interesting discussions. This work was commenced while the author was a Visiting Professor at the University of Western Ontario.

# Pacific equatorial pressure gradient and Indian monsoon rainfall

SEA surface temperature (SST) anomalies are known to affect atmospheric flow patterns considerably. The Indian monsoon circulation is induced by the thermal contrast between the Asian continent and the Pacific and Indian oceans and by the orography of the Himalayas, so large scale SST anomalies are likely to affect the monsoon circulation, but after some time lag.

In recent years SST anomalies over the Pacific have been associated with Walker's Southern Oscillation1,2. We find that the factor (Mataveri-Darwin) pressure difference used by Ouinn and Burt as a measure of the strength of the Southern Oscillation is also quite useful in predicting monsoon rainfall.

Figure 1 shows the relationship between the seasonal (June-September) monsoon rainfall of north-west India and the mean

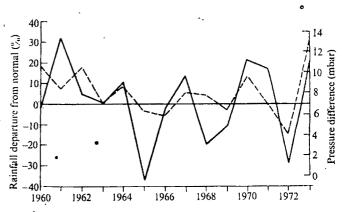

Fig. 1 Relationship between rainfall and pressure gradient. -Departure from normal (%) for seasonal (June-September) rainfall in north-west India. — —, Mean Pacific pressure gradient (Mataveri-Darwin) during April and May.

Pacific pressure gradient (Mataveri-Darwin) during April and May, from 1960 to 1973. There is some correspondence between the two curves (except for 1968) and the large contrast between the drought year of 1972 and the good monsoon year of 1973 is evident in both cases. In the drought years of 1972, 1965 and 1966, this average pressure difference fell below 7 mbar. The area of that part of the pressure gradient curve below 8 mbar, as used by Quinn and Burt, seems to be a good indicator. In 1972, an El Nino year, the pressure difference fell to as low as 0.5 mbar in May, whereas it was 7.6 mbar in May 1973. Pacific typhoon activity was also much above normal in 1972 but below normal in 1973.

## New pole for early opening of South Atlantic

Using the trends of equatorial, marginal fracture ridges, Le Pichon and Hayes<sup>1</sup> proposed an early phase for the opening of the South Atlantic, with a pole of rotation at 21.5°N, 14°W with respect to Africa. Francheteau and Le Pichon<sup>2</sup> tested this plate tectonic model with the whole South Atlantic and assumed that there is a relationship between continental margin offsets, the subsidence of coastal basins, and adjacent marginal fracture zones. We have studied extensions of fracture zones

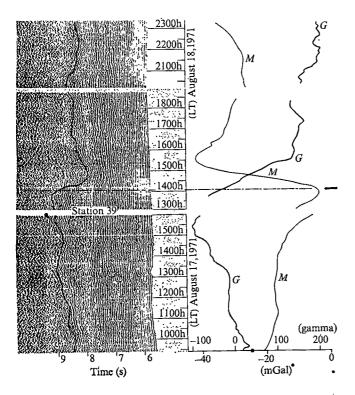

Fig. 1 Seismic profile across the Chain Fracture Zone south of Togo (location on Fig. 2). Note the difference in level of the acoustical basement under a thick sedimentary cover. The free air gravity anomaly is of the order of 40 mGal. The arrow indicates the theoretical location used for the determination of the trend of the fracture zone. M, Magnetic curve; G, gravity

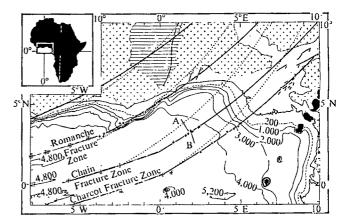

Fig. 2 Eastern Gulf of Guinea. Bathymetric contours (m) from E. Uchupi (unpublished); geological sketch from the geological map of Africa19. Crosses, cratonic area; hatched, Palaeozoic platform; dotted, Mesozoic to Recent basins; black area, Cameroon volcanic line. Heavy crosses, positions of geophysical features (from seismic, gravity, or magnetic surveys) used for computation of the new early pole of opening. Heavy black lines, portion of small circles about the new early pole along the Saint-Paul, Romanche, Chain and Charcot Fracture zones. Note the good agreement between the extension of the two last fracture zones and the main geological trends in Nigeria. Dotted lines, portions of small circles about the previously proposed pole of opening. Note the discrepancies with the geological trends in the Benoue Trough area. Double lines, posterior fracture zone trends. A-B indicates profile of Fig. 1.

in the Gulf of Guinea and adjacent continental margins and have determined a new early opening pole that differs markedly from the one previously determined.

Thanks to deeper penetration seismic techniques, extensions of the well known equatorial fracture zones3 have been traced into the Gulf of Guinea<sup>4-7</sup> under a thick sedimentary cover mostly related to the Niger Delta. Figure 1 shows a seismic section across the extension of the Chain Fracture zone. It has been proposed8 that the position of the inflexion point on the regional free-air anomaly curve corresponds to the main changes in the average basement level; consequently, seismic and gravity criteria have been used both together and separately to locate the position of the fracture zone. A structural trend called the Charcot Fracture Zone7,9,10 has been discovered just south-west of this delta (Fig. 1).

We have re-interpreted these results to obtain a better knowledge of the early opening phase of the Gulf of Guinea and consequently of the South Atlantic. The positions determined of the main geophysical features considered here are shown on Fig. 1. The Saint Paul Fracture Zone itself has not been taken into account, mainly because of its complex structural pattern near the Liberian continental margin<sup>11</sup>. The trend of the Chain Fracture Zone previously inferred from bathymetric data1,5 is not compatible with our data (Figs 1 and 2). Parameters of our new pole are 32°N, 20°W (with a standard deviation of 6 km).

The great circle defined by the two poles of rotation (21.5°N, 14°W and 32°N, 20°W) cuts across the Liberian continental margin, the Walvis Ridge and the Aghulas Fracture Zone<sup>12,13</sup> along a line close to the boundary that existed between Africa and South America before the opening of the ocean. Consequently, small circles about the two poles of rotation are tangential to each other, especially in the area where the great circle lies close to preopening boundaries. They diverge as the distance from the great circle increases, as in the eastern part of the Gulf of Guinea. Moreover, this effect decreases as the distance from the pole increases.

Figure 2 shows the small circles about each pole of rotation in the Gulf of Guinea. The direction of early opening which we propose fits well with the Liberian-Ivory Coast continental slope and with the limit of the Togo-Dahomev Basin. It also

agrees much better than did the previously proposed direction with the broad geological structure in Nigeria. It allows the extension of the Chain Fracture Zone to be related more easily with the northern hinge line of the Niger Delta<sup>14</sup> and the northern limit of the Benoue Trough<sup>15</sup>. The Charcot Fracture Zone seems to correspond well with the complex Abakiliki area in southern Nigeria16.

Figure 3a shows the good agreement between small circles about the new pole (32°N, 20°W), and fracture trends in the vicinity of the Liberian continental margin<sup>11</sup>. Figure 3b and crepresent, respectively, the eastermost section of the Walvis Ridge<sup>17</sup> and the Agulhas Fracture Zone<sup>12,13,18</sup> on which a computed theoretical direction from the new pole has been superimposed. As expected from the orientation of the great

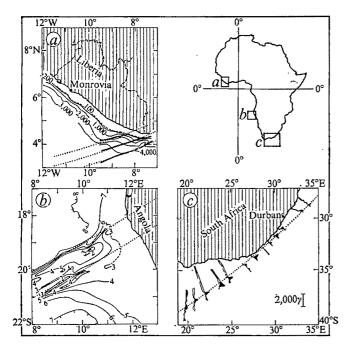

Fig. 3 Comparison between some western South Atlantic marginal structures and the new theoretical direction (small circles about a pole at 32°N, 20°W). a, Liberian continental margins (depth contours in metres) and the Saint-Paul, Cape Palmas, Grand Cass fracture zones<sup>10</sup>; b, depth (in seconds) of easternmost Walvis Ridge basement<sup>6</sup>; magnetic anomalies in the Agulhas Fracture Zone.

circle and the distance from the poles, the agreement in both cases is good. It is interesting to note that the easternmost Agulhas Fracture Zone differs somewhat from the theoretical direction but it should be specified that this fracture zone has for the most part been inferred from magnetic anomalies13. Those anomalies could be related partly to the continentaloceanic crust boundary instead of being representative of only the fracture zone itself.

Although in many cases this newly established evidence will have to be taken into account in any detailed reconstruction of the opening of the Atlantic, the conclusions of Francheteau and Le Pichon<sup>2</sup> still seem to be valid.

We thank the scientific staffs of the RV Atlantis II and RV Jean Charcot for the acquisition and the use of the data. X. Le Pichon and V. Renard critically reviewed this paper.

# Magnetic polarity of **Explorer Ridge basalts**

THE Vine-Matthews hypothesis1 connects geomagnetic polarity reversals with marine magnetic anomalies through the process of seafloor spreading. This hypothesis requires a one-to-one correlation between the sign of a given marine magnetic anomaly and the magnetic polarity of underlying oceanic basalt. Because properly oriented samples are lacking, however, this feature remains virtually untested in spite of its crucial significance.

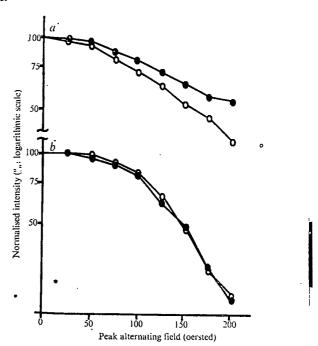

Fig. 1 Demagnetisation curves interpreted as: a, reversed polarity (specimen 717002A); b, normal polarity (specimen 701520A). The size of the symbols represents experimental uncertainty. ●, NRM; ○, ARM acquired in a bias field of 0.58 oersted and a peak alternating field of 1,800 oersted.

\* Best satellite Navigator fix for terminus of dredge haul.

Under certain circumstances<sup>2,3</sup>, the polarity of the original remanence of unoriented dredged samples can be recovered. It is essential for the success of the method that there be present secondary magnetic components in the samples resulting from magnetic viscosity of the oceanic basalts in the presence of the recent geomagnetic field, and these can be expected to parallel the primary remanence of normal polarity basalts and to oppose that of reversed material, provided that the rocks have remained in situ. Under appropriate conditions this may lead to a detectable difference between the alternating field demagnetisation curves of natural remanence (NRM) and laboratory induced remanence; anhysteretic remanence (ARM) is used to avoid problems associated with reheating. Irving<sup>2</sup> has suggested that a normalised NRM curve lying significantly above the corresponding ARM curve is indicative of reversed primary remanence.

This method (and slight variations of it) has been applied to samples from the Mid-Atlantic Ridge. Agreement has been found<sup>4,5</sup> between inferred polarity and overhead anomaly in 20 out of 41 specimens. A positive correlation has been found in 16 out of 20 specimens dredged from the Juan de Fuca Ridge<sup>6</sup>.

We are completing a study of the magnetic properties of a suite of basalt samples dredged from the Explorer Ridge which represents an extension of the Juan de Fuca Ridge north of the Sovanco Fracture Zone<sup>7,8</sup>. The details will appear elsewhere; here, we report a substantial correspondence between inferred magnetic polarities and those predicted by the Vine-Matthews hypothesis. Twenty-six basalt samples(one specimen per sample) from five separate dredge hauls have been investigated. The locations of the five hauls (Table 1) lie within the central positive magnetic anomaly and the adjacent negative anomaly<sup>9,10</sup>. They are within 40 km of active spreading centres and range in age from 0-2 Myr.

We have found that the region between 0 and 200 oersted is

the most useful part of the coercivity spectrum as the ARMs become weak and generally unstable at higher peak fields. Results indicating clear cases of each polarity are given as examples (Fig. 1). The 26 specimens have been classified according to the relative hardness of their ARM and NRM demagnetisation curves.

One must seek assurance that any apparent differences between NRM and ARM coercivity spectra are significant compared with experimental uncertainty. For strongly magnetised rocks, this is no better than about 2%. To be conservative we have sought an average difference of 4% to establish firmly any divergence of the two curves, although Table 1 indicates that this choice is not too critical for most of the samples. In addition, the alternating field (a.f.) treatment to which the two curves should be normalised must be investigated fully. This second point arises because of the magnetic noise generated by additional short-lived components of magnetisation acquired between departure from outcrop and measurement<sup>2</sup> These unwanted viscous components can be effectively filtered off by normalising to successively higher fields<sup>2</sup>. To test the difference, or lack of difference between NRM and ARM, and also to investigate the effect of different normalising fields, the mean difference,  $\Delta_h$  (ref. 5) between the two spectra at the various treatments has been calculated. The values of  $\Delta$  at different normalising fields, h, are given in Table 1. As the appropriate normalising field is not known in advance we first of all classified those cases in which all normalisations yielded the same inferred polarity. Thus, 14 specimens could be regarded as definitely normal and 7 specimens as definitely reversed. A further two specimens (719202A and 719203A) showed generally large positive differences with isolated dips below +4%: these are very probably reversed. Of the remaining three specimens, 700425A is classified as normal as its  $\Delta$  values exceeds +4%(by very small margins) only at 0 and 25 oersted. Specimens

<sup>†</sup> From data of Raff and Mason<sup>13</sup>; range given where hauls crossed steep gradients. ‡ From interpretations of magnetic anomalies by Vine<sup>9</sup> and Silver<sup>10</sup>.

 $<sup>\</sup>delta \Delta h = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum \delta_i$ , where h is the normalising field; N is the number of demagnetising steps between h and 200 oersted, and  $\delta_i = \frac{100}{N} \sum_i \delta_i$ , where h is the normalising field; (normalised NRM-normalised ARM) at field i.

<sup>¶</sup> Demagnetising step inadverdently omitted.

Three cases, discussed in the text, have tentative polarity assignments only and are designated by parentheses.

701701A and 719210A are tentatively classified as reversed because their demagnetisation curves begin to diverge significantly at higher fields.

We therefore feel that 23 of the 26 assigned polarities are quite firmly established; the remaining three are rather tentative. The significant result is that a total of 20 out of the 23 specimens (or 22 out of 26 if the dubious assignments are included) yield polarities in agreement with the overhead anomaly (Table 1), lending strong support to the Vine-Matthews hypothesis. The few cases of disagreement give no cause for alarm. Indeed, a small percentage of samples of opposite polarity are expected from gravity-transported boulders and from contamination because of the finite width of intrusive activity at accreting plate boundaries11,12.

We thank the officers and crews of CFAV Endeavor and CSS Parizeau, and R. L. Chase, who directed the cruises. We also thank A. B. Reid, D. K. Bingham, D. I. Gough and J. A. Jacobs for assistance and advice. Financial assistance was provided by the National Research Council of Canada.

# 3,800-Myr granitic gneiss in south-western Minnesota

We have previously arrived at an age of 3,550 Myr for granitic<sup>1</sup> gneiss in the vicinities of Morton and Montevideo in the Minnesota River valley, south-western Minnesota. We now report new Rb-Sr analyses (Table 1) and an age of 3,800 Myr for the fine grained foliated phase of the Montevideo Gneiss of Lund<sup>2</sup>. The rocks have undergone a complex history of metamorphism which remains to be deciphered, but the age determinations reveal that the geological mapping and previous interpretations did not provide a proper basis for sampling.

Table 1 Analytical data						
Sample no.	p.p.m	. (weight)	Ratio (atomic)			
•	Rb Î	Sr	87Rb/86Sr	87Sr/86Sr		
KA-209	79.4	204.1	1.132	0.7619

609	71.7	339.0	0.6136	0.7324		
	, ,	557.0	0.0150	0.7524		

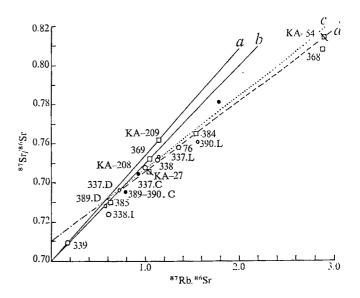

Fig. 1 Rb-Sr isochron diagram of whole-rock (squares) and Kfeldspar samples (crossed squares) from the Montevideo Gneiss and whole-rock samples (large open circles) from the Morton Gneiss (small open circles, samples in composites; small closed circles, composites). (From Goldich et al.\(^1\).) a, 3,800 Myr (0.700); b, 3,550 Myr; c, 2,650 Myr (0.710); d, 2,550 Myr.

Our original age of 3,550 Myr. ( $t_{\downarrow} = 50 \times 10^9 \text{ yr}$ ) was based on our interpretation of discordant U-Pb zircon ages and a Rb-Sr age computed for three whole-rock samples (Fig. 1, numbers KA-209, 369, 385). The 2,650-Myr isochron (Fig. 1) represents a time of high grade (granulite facies) metamorphism and is based on Rb-Sr rock-mineral isochrons and on nearly concordant U-Pb zircon ages1. The 2,550-Myr isochron approximates the time of uncovering and of stabilisation of the Rb-Sr system in the K-feldspar. A line through the points for sample KA-209 from the Montevideo Gneiss and sample 339 from the Morton Gneiss gives an age of 3,800 Myr with an initial 87Sr/86Sr of 0.700 (Fig. 1).

We did not previously attach any significance to this line because only two data points were involved. Of the six new samples from the Montevideo Gneiss, however, four lie on the 3,800-Myr isochron and two above this line (Fig. 2). The difference between the measured ratios for samples 607 and KA-54 and the other ratios are real and outside analytical error  $(\pm 1\% \text{ for } {}^{87}\text{Rb}/{}^{86}\text{Sr} \text{ and } \pm 0.0002 \text{ for } {}^{87}\text{Sr}/{}^{86}\text{Sr}); \text{ hence,}$ inclusion of these samples in an isochron plot is not desirable and some sort of geological explanation is required. The most obvious one is that during the complex history of metamorphism and igneous activity some metasomatic action was involved; for example, Rb and Sr moved among the rock units creating an open system. A gain in Rb or loss in radiogenic 87Sr would lower the ages and explain the scatter of the whole-rock and K-feldspar points in Fig. 1. The apparent ages of the gneiss samples (Fig. 2) therefore must be considered minimum values. If it is argued that the apparent ages are too old, the explanation must invoke either loss of Rb or gain of radiogenic 87Sr. We favour such an explanation with a net gain of 87Sr for samples KA-54 and 607.

A least squares calculation, excluding KA-54, 607 and 339, gives an age of 3,950  $\pm$  70 Myr (2 $\sigma$ ) with an initial  $^{87}$ Sr/ $^{86}$ Sr ratio of 0.698  $\pm$  0.004, exceptionably low for terrestrial rocks. We, therefore, prefer to include sample 339 from the Morton Gneiss as a guide to the initial ratio of 0.700 and an age of 3,800 Myr.

The history of the Precambrian rocks in the Minnesota River valley has some marked resemblances to the events that have been dated3 in the ancient rocks of West Greenland. As in Greenland, the oldest rocks in south-western Minnesota

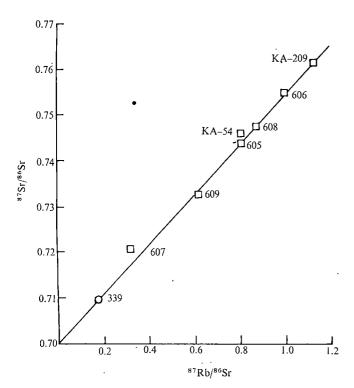

Fig. 2 Whole-rock samples from the foliated phase of the Montevideo Gneiss ([]). O, Morton Gneiss—3,800 Myr (0,700).

are gneisses ranging in composition from tonalite to granodiorite and quartz monzonite. These were intruded by granite and pegmatite of one or more periods of magmatic activity. Preliminary results indicate an age of approximately 3,000 Myr for some of the massive layers of granite which were formerly considered an original component of the Montevideo Gneiss1. Foliated and massive phases were folded together during the high-grade metamorphic event 2,650 Myr ago, at which time large volumes of granite were emplaced in south-western Minnesota. Basaltic dykes were intruded in several periods, the older ones being involved in the 2,650-Myr metamorphism and predating the granitic activity of approximately 3,000 Myr ago. Some dykes are much younger and were intruded before the emplacement of granite 1,850 Myr ago.

Work is in progress on U-Pb and Rb-Sr dating of the old gneissic rocks and of the younger rock units. The work at Northern Illinois University was supported by a grant from the National Science Foundation. We thank G. R. Himmelberg and R. L. Bauer of the University of Missouri for help in the sampling.

### Anomalies in particle shape during seeded growth of polystyrene latices

We have observed unusual changes in latex particle shape during the 'seeded' growth of polystyrene latices in emulsifierfree systems (Fig. 1a). To our knowledge this has not previously been recorded.

Polystyrene latices may be grown in the absence of emulsifier1,2 (Table 1); however, the ultimate size of the latex produced is limited. In an effort to obtain larger particles, using an emulsifier-free technique, we used a two-stage process whereby a latex of selected size was utilised as the 'seed' to grow larger particles.

Table 1 Normal growth process						
Time after initiation (min)	Size (nm)	Standard deviation (nm)	B <sub>1</sub>	$B_2$		
1 5 15 30 60 90 120 175 275 302 330	20.3 37.5 85.3 101.4 145 176 204 244 308 327 347	4.2 2.7 3.7 2.9 3.3 2.0 4.2 2.0 3.5 4.0	1.69 0.03 0 0.05 0.11 0.61 0.14 0.01 0.09 0.09	6.02 3.04 2.57 2.33 2.93 2.45 3.49 2.29 2.92 1.83 2.35		
330 1,257	. 435	3.7 4.0	0 0.45	2.35 6.59		

 $B_1$  and  $B_2$  describe the skewness and kurtosis of the particle size distribution and should be 0 and 3 for normal distribution3.

In a typical seeded growth process, a sample (50 g of 51% w/w polystyrene latex of diameter 520  $\pm$  11 nm) was agitated for 24 h at 70  $\pm$  0.2° C with 25 g of styrene monomer, 54 g distilled water and 0.02079 g potassium persulphate free radical initiator dissolved in 19.5 g distilled water. Samples were taken at intervals and sizes determined by means of electron microscopy (Table 2). The latex particles increased in size, through stages which were themselves highly monodisperse, to a diameter of 606  $\pm$  5 nm, an increase of approximately 20%.

Two hours after the start of the experiment, new polymer particles of diameter about 25 nm appeared. These particles formed agglomerates, which in turn attached themselves to the original polymer seed spheres. Since no small particles were present at the end of the reaction, we inferred that they had contributed to the growth of the 'seed'. After 4 h, incomplete spheres, eroded to varying degrees, were observed and from

	Table 2	Seeded growt	h process	,
Time after initiation (min)	Size (nm)	Standard deviation (nm)	$B_1$	$B_2$
0 22 58 133 182 244 301 362 1,440	520 (520) 525 526 522 (528) 542 (531) 542 (540) 562 589 625 (606)	11.0 (11.0) 5.0 6.0 5.0 (4.0) 7.0 (5.0) 4.0 (9.0) 8.0 30.0 6.0 (5.0)	0.05 (0.05) 0.05 0.16 0 (0.22) 6.02 (0.54) 0.62 (1.29) 0.09 3.41 0.33 (0.01)	4.00 (4.00) 4.08 3.75 1.99 (2.46) 2.42 (2.56) 3.18 (4.09) 2.79 7.72 5.96 (2.07)

Values in parentheses refer to process where all reactants were added and polymerisation begun immediately. See also legend for Table 1.

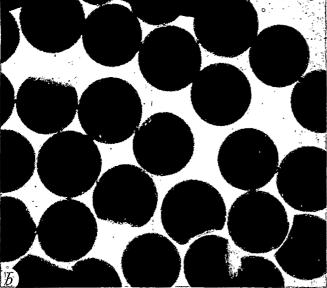

Fig. 1 a, Eroded polystyrene latex particles produced during an emulsifier-free seeded growth process. Seed latex  $520 \pm 11$  nm 362 min after initiation of reaction, size  $589 \pm 30$  nm. b, Eroded particles at high accelerating voltage (100 KV) to reveal internal detail.

measurements we concluded that, in some cases, erosion must have involved some of the original 'seed'. This dissolution of hardened polymer spheres is difficult to explain. Erosion increased until, after 6 h, the phenomenon was most pronounced with large proportions of some spheres eroded away, for example Fig. 1a, arrow 1. At the end of the polymerisation (24 h), however, the erosion was no longer seen, the spheres having apparently reformed.

Detailed examination in the electron microscope at higher accelerating voltage (Fig. 1b) revealed the presence of eroded particles with varying orientations and it is possible that the majority of particles was affected. The formation of incomplete latex spheres did not seem to be a consequence of specimen preparation and subsequent electron microscopy since it was not recorded during normal growth processes.

In order to study the possible effect of the monomer on swelling and erosion of the polymer particles, a sample of 'seed' latex was left in contact with monomer overnight at room temperature before the initiator was added and the 24 h polymerisation carried out. A similar abnormal growth process was observed. (A sample of this particular grown latex (625  $\pm$  6 nm) was stored for 5 months at room temperature after which no further erosion, caused by storage in unreacted monomer, was observed.)

We note that in some cases the incomplete spheres appeared to originate from groups of two or more, where clear interlocking occurred (Fig. 1a, arrow 2). Examination of numerous particles, however, failed to reveal any spheres with two or more eroded portions. Such particles might be expected as the result of the break-up of fused spheres.

### Oriented glass ceramic fibre

Longitudinal velocity gradients in a flowing system have a powerful orienting influence on macromolecules and have been used to align polyethylene chains immediately before crystallisation<sup>1</sup> and from the melt<sup>2</sup>. Corning 119 SCR is a glass which crystallises to a glass ceramic containing fluorophlogopite (mica) as the principal crystalline phase. By subjecting it to pure extensional flow during crystallisation, strict alignment of the fluorophlogopite crystals has been achieved. Once produced, the alignment is maintained during subsequent drawing down to fibre diameters of less than 100 µm.

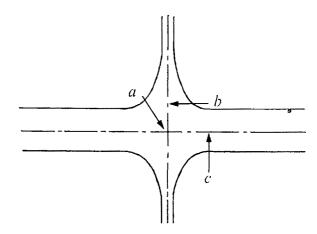

Fig. 1 Flow produced by impinging jets. a, Centre of symmetry; b, symmetry plane; c, symmetry axis.

A large strain rate, free from the complicating effects of rotation, exists along the axis (and in the plane of symmetry) of two opposed fluid jets meeting as shown in Fig. 1 (refs 1 and 3). Along the axis, the fluid velocity is zero at the centre of symmetry, increasing to a velocity  $\nu$ —equal to that for unrestricted flow—at a distance of approximately d/2, where d is the bore diameter

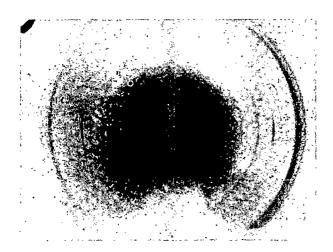

Fig. 2 X-ray pattern from an extruded rod. The rod axis is

of the jets. The corresponding strain rate is  $\varepsilon \sim -2\nu/d$ ; for example,  $2 \times 10^3$  s<sup>-1</sup> for v = 1 m s<sup>-1</sup> and d = 1 mm.

The same kind of flow field is obtained by extruding fluid through opposed dies; v is then the speed of the fluid leaving the dies and is determined by the speed of the extrusion ram and the bore diameters of the container and dies.

The extrusion press for this experiment consists of a stainless steel container placed inside the coil of a high frequency induction furnace and between the cross head and base plate of a tensile testing machine. Lowering the cross head pushes a pair of rams into two vertical channels which are interconnected by a

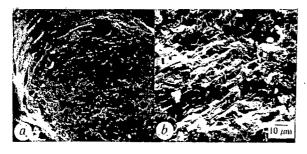

Fig. 3 Scanning electron micrographs of fracture surfaces. a, Normal to the axis of a 150  $\mu$ m diameter fibre drawn from a 2 mm diameter extruded rod; b, oblique to the axis of an extruded rod subsequently fully crystallised by annealing.

horizontal channel across the middle of the container. All three channels are filled with glass; the dies are oriented vertically and countersunk into the horizontal channel. Both the radial velocity gradient of the fluid entering the dies and the shearing flow of the fluid within the dies are also expected to have an orienting effect on the crystal nuclei.

Figure 2 shows the Laue transmission X-ray diffraction pattern from a rod extruded at the crystallisation temperature (950 °C) using an interdie strain rate of 165 s<sup>-1</sup>. Fluorophlogopite is hexagonal4 and the basal plane reflections 0003 and 0006 each take the form of a pair of arcs parallel to the rod axis. All other reflections occur as Debye-Scherrer rings because the crystals are oriented randomly about the hexad axis. Identical patterns have been obtained from rods extruded and then drawn down to diameters of 150 µm and 75 µm.

The alignment of crystals can be observed directly by scanning electron microscopy of fracture surfaces (Fig. 3a). The density of crystals is uniform except very near the fibre surface where it falls to almost zero. In drawn samples, the surface

contains a high density of shrinkage hollows. Completion of the crystallisation treatment, by annealing at 950° C, produces some growth of the oriented crystals plus growth of new and, therefore, unoriented nuclei. This second generation of crystals is evident in Fig. 3b.

## The direct measurement of sulphur deposition on bare soil

THREE one-thousandth acre gauges, respectively 20, 40 and 60 inches deep were made at Rothamsted Experimental Station in 1870 by Lawes and Gilbert<sup>1</sup>. Since 1870 the soil in the drainage gauges has not received any fertiliser and has not been cropped. Amounts of nitrogen mineralised annually2 have fallen to about 7 kg ha<sup>-1</sup> and from this we have calculated that sulphur mineralised is about 1 kg ha-1 annually. Chemical analysis showed that the drainage water contains twice as much sulphur as is deposited in rain. A direct measurement of the dry deposition of sulphur was made to see if this satisfactorily accounted for the discrepancy.

Two grams of air-dried sieved soil (0.5 mm), with a total sulphur content of 9.2 μg S g<sup>-1</sup>, were exposed in Petri dishes inside a standard Stevenson meteorological screen at three sites, Rothamsted (Herts.), Woburn (Beds.) and Saxmundham (Suffolk), in mid-February 1974 for 57 to 77 d. Sulphur deposition rates were calculated from the increases in total sulphur content after exposure (Table 1). Air sulphur concentrations were measured at Woburn Experimental Station and Framlingham (near Saxmundham) and identical deposition velocities (Vg) calculated for both. Since, at this time<sup>3</sup>, the measured deposition rates would be close to the annual means, we have calculated depositions (kg S ha<sup>-1</sup>) of 18.1 (Saxmundham), 27.5 (Rothamsted) and 65 (Woburn) annually. An independent check on the Rothamsted figure (27.5 kg S ha<sup>-1</sup>) was made from the analysis of drainage water from the 20-inch deep, one-

Table 1 The period of exposure, increase and deposition rate of sulphur to bare soil at three sites and the air sulphur concentration and deposition velocity for two of the sites

	Saxmundham*	Rothamsted	Woburn

<sup>\*</sup> S air concentration measured at Framlingham.

<sup>†</sup> S air concentration not measured at Rothamsted.

thousandth acre drain gauge during 1969, the hundredth year. The SO<sub>4</sub> sulphur collected in drainage through this gauge was 58.36 kg S ha<sup>-1</sup>. Subtracting sulphur content of rainwater (33.02 kg S ha-1) we obtain 25.34 kg S ha-1 which represents dry deposition plus a small amount of sulphur mineralised from soil organic matter. Ignoring mineralised sulphur, we have calculated a mean sulphur deposition rate of 8.03 × 10<sup>-12</sup> g cm<sup>-2</sup> s<sup>-1</sup> yr<sup>-1</sup> which, allowing for differences in air SO<sub>2</sub> concentrations between 1969 and 1974, agrees well with the figure obtained here  $(8.72 \times 10^{-12} \text{ g cm}^{-2} \text{ s}^{-1} \text{ S})$ .

Deposition velocities of sulphur with respect to vegetation have been shown to be two or three times faster4,5 so that, the amount of sulphur deposited on vegetation would be correspondingly greater than the amounts measured here.

### Fluorocarbon anaesthetics break hydrogen bonds

Many fluorocarbon derivatives that contain higher halogens dissociate hydrogen bonds of the N-H-N, O-H-O, S-H-S, N-H-O=C type which are similar to those occurring in living organisms. A parallelism exists between this property of fluorocarbons and their anaesthetic potency. Their interference with cell division might also be related to it.

Halothane (CF<sub>3</sub>-CHClBr) is the most widely used inhalation anaesthetic1-3. The mechanism of the anaesthetic action of these compounds has not yet been elucidated, although anaesthetic potency has been related to lipid solubility<sup>4,5</sup>, clathratehydrate formation<sup>6,7</sup>, and interaction with proteins to produce conformational changes<sup>8-10</sup>. We have observed that fluorocarbons can 'break' hydrogen bonds11,12 and have investigated the relationships between this property and their anaesthetic properties by measuring infrared spectra of systems which are hydrogen bonded in solvents of chlorine, bromine or iodine containing fluorocarbons. These systems were hydrogenbonded amides (N-ethylacetamide, N-methylbenzamide, acetanilide, δ-valerolactam), alcohols, amines and thiols. An order of potency of hydrogen-bond breaking has been established from the infrared band intensities: F < Cl < Br < I. This applies to all N-H-N, O-H-O, S-H-S and N-H-O=C type hydrogen bonds. It is very significant, in our opinion, that F < Cl < Br < I is also the order of increasing anaesthetic potency1,3.

Another observation deserves consideration. If the fluorocarbon contains a hydrogen, its potency of hydrogen-bond breaking greatly increases. Although CF<sub>3</sub>-CCl<sub>3</sub> has no significant ability to break hydrogen-bonds CF3-CHCl2 is about as potent as halothane (see Fig. 1).

In view of these two parallels between hydrogen-bond breaking and anaesthetic potencies it is natural to speculate that the breaking of hydrogen bonds is an important step in the mechanism of anaesthesia which has been induced by fluorocarbons. The hydrogen bonds that may be 'broken' can be water-water or water-protein bonds or hydrogen bonds within

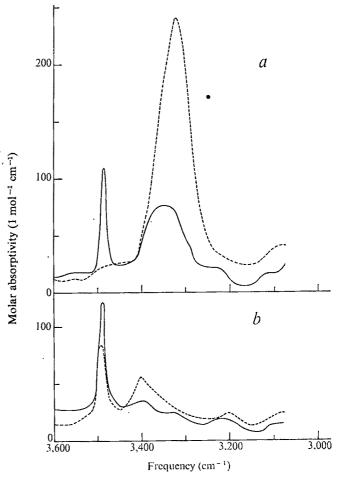

Fig. 1 The infrared spectra of a 0.045 M solution of N-methylpivalamide in a 1:1 mixture of CCl<sub>3</sub>F and methylcyclohexane (dashed line) and in the same solvent with 1.02 M CF<sub>3</sub>-CHCl<sub>2</sub> added (solid line). a, At -80° C; b, at 23° C.

the protein and nucleic acid structures; they all have energies similar to those of our model systems. In some cases the hydrogen bonds may actually be dissociated, in others a lesser perturbation may be sufficient.

The importance of this observation may well go beyond the mechanism of anaesthesia. Nunn et al.13, and Jackson14 have reported that halothane arrests mitosis. Mitosis goes through several phases involving both the breaking and the formation of the hydrogen bonds which keep the two parts of the nucleic acid double helix together. In view of the potent ability of fluorocarbon anaesthetics to break hydrogen bonds it is tempting to speculate that the former interfere with cell division by perturbing or breaking hydrogen bonds around or in the helices, or in the mitotic spindle.

We thank the National Research Council of Canada for financial help and the E. I. Du Pont de Nemours Company of Wilmington, Delaware, for a grant. Our special thanks go to Dr R. L. McCarthy and Dr C. S. Hoffman of Du Pont.

# Radiocarbon chronology for Seibal, Guatemala

The significance of the study paper reported here is the fact that the origins of Maya civilisation are pushed much further back into the past. Radiocarbon dating of the earliest and latest states of the Mayan 'city' centre of Seibal indicate an origin as early as 900 BC, declining by about 1000 AD. This discovery narrows the interval between the beginning of lowland Maya occupation and the Olmec centres on the Gulf of Mexico, allowing for the coexistence of quite different cultures in relatively close geographical proximity.

Seibal, located on a bluff in the upper Usumacinta-Pasión river drainage of Guatemala (approximately 16°N, 90°W), is one of the important lowland Maya 'city' centres excavated in recent years by Harvard's Peabody Museum<sup>1,2</sup>. Radiocarbon dating of charcoal and bone samples at the University of California (UCLA) indicate that the city has been in existence for almost 2,000 yr, roughly symmetric about the AD-BC division3. Seibal's time was over by 10.5.0.0.0 katun, equivalent to 928 AD, even though some population lingered on for some time. A more detailed chronology is based upon the following radiocarbon measurements in conjunction, where applicable, with Mayan dates, which in turn are related to our present calendar via the Goodman-Martinez-Thompson correlation (Fig. 1). All radiocarbon samples were pretreated to remove impurities and analysed, where appropriate, by their collagen content, precautions being taken for isotopic purity<sup>4</sup>. A comparison showing the concordance of charcoal- and collagenbased radiocarbon dates has appeared elsewhere<sup>5</sup>.

The earliest occupation discovered belongs to the Real Xe phase of the Middle Preclassic Period. In particular, a sample of charcoal was dated associated with pottery vessel 2 in cache 7 of Central Plaza group A. This cache was actually located beneath several preclassic floors and definitely sealed in a Real Xe phase context. It consisted of a cruciform arrangement of pottery and jades. Among the latter was a blood letter resembling an ice pick in shape, a style associated with the Olmec horizon and Olmec sites of the Gulf Coast. These Olmec sites date from as early as about 1300 BC and persist as late as the fifth century BC. For the purposes of this paper the dates have been tree-ring calibrated, based on an earlier publication which did not include this calibration.

Previous archaeological estimates of the date of the Xe ceramic sphere derived from radiocarbon dates at Altar de Sacrificios<sup>7</sup> and other lines of evidence, were in the range 900-600 BC. The present charcoal date of 2,610 ±75 yr (UCLA: 1437; S-382b) can be calibrated to correspond to an age of 900 BC; this, in a general way, is in line with estimates for the early Middle Preclassic Period of Mesoamerica as a whole<sup>8,9</sup>. In relation to chronology, Real Xe and the Xe ceramic sphere<sup>10</sup> immediately precede the Mamom ceramic sphere.

After the Real Xe phase, the next date obtained is based on a bone sample from burial 19 found beneath a platform in front of structure D-3. Associated pottery places this burial in the Tepejilote phase of the Tepeu ceramic sphere. The particular pottery types indicate a Tepeu 2 placement, or, at the earliest, a late Tepeu 1. The radiocarbon'date obtained from collagen is 1,490 ± 320 yr (UCLA: 1640D; S-1316) corresponding to a calibrated age of 500 Ad. Because of the small sample size the statistical error is larger than desirable, which explains why this particular date does not agree with the archaeological estimate of about 675-830 Ad. This is based on the 11.16.0.0.0 correlation and ceramic styles<sup>11</sup>, with a preference for the earlier end of this range.

The next datum is a bone sample obtained from burial 17 located in structure A-2. The structural context indicated an Early Classic dating, although the pottery with the burial pertained to the Tepejilote phase and could very well have been the earliest part of that phase, equivalent to a Tepeu 1 date. The radiocarbon date of 1,420 ± 95 yr (UCLA: 1640C; S-1193) corresponded to a calibrated age of 600 AD, in agreement with the inception of Tepeu 1 in the 11.16.0.0.0 correlation.

Burnt human bone from a mass burial (No. 4) in structure A-13 provided the next date. The radiocarbon date is 1,100  $\pm$  100 (UCLA: 1,640F; S-410) which can be calibrated to 930 AD. Structure A-13 is an interesting small mound or platform that seems to have been designed to receive a mass interment. It is located immediately next to a large ball-court in the Central Plaza of group A. Perhaps the structure does indeed contain the sacrificed remains of persons who had been in some way involved with the game and actually may have been the defeated team. On the basis of associated potsherds, the mass burial can be dated to the Bayal phase of the site's history. Bayal, which can be placed at about 10.0.0.0.0 to 10.5.0.0.0 (830-928 AD), was a time of considerable ceremonial activity at Seibal including architectural construction and dedication of stelae, with monuments dated as late as 10.3.0.0.0 (889 AD). Characteristic of the Bayal phase is the fine Orange pottery of group Y or Altar series.

Similarly, a bone sample from burial 12, which was found below the patio floor of structure 31A, again confirmed the Bayal phase. The building is a small one on the outer periphery of Seibal, as opposed to the main ceremonial centre. The radiocarbon date is  $1,000 \pm 65$ , calibrated at 1000 AD (UCLA: 1640A), all the associated sherds belong to the Bayal phase, making the radiocabon dating late for the Bayal period of 830-928 AD, although it is quite possible that some of the outlying structures at Seibal were occupied for a few decades beyond the estimated date of 10.5.0.0.0 katun (928 AD). Activities in the main ceremonial centre were over by 10.4.0.0.0 or 10.5.0.0.0 but secular life may have continued in the outskirts.

Additional confirmation for the age of the Bayal phase is derived from a bone sample from burial 13, found inside a small structure (26d) also on the periphery. An associated burial and its surrounding sherd also indicate the Bayal phase.

Table 1 Correlation between ceramic spheres, phases and tree-ring calibrated radiocarbon dates at Seibal

Ceramic sphere	Phase	Calibrated radiocarbon date (12)
Boca	Bayal	1050 AD 1000 930
Tepeu	Tepejilote	600 (500) AD
Tzakol Chicanel Mamom		
Xe	Real Xe	900 вс

Early start of Real Xe at Seibal narrows the interval between the beginning of lowland Maya occupation and Olmec sites on the Gulf of Mexico.

The radiocarbon date is 940+70 (UCLA: 1640B) calibrated to 1050 AD, in agreement with previous considerations.

On balance, the calibrated radiocarbon dates agree well with lowland Maya Middle Preclassic and Terminal Late Classic estimates. The latter are consistent with an 11.16.0.0.0 correlation of Maya and Christian calendars. Two dates, one from the earlier late Classic Period, the other from what would appear to be the equivalents of a Tepeu 1 or 2 context, are a little more difficult to reconcile with the 11.16.0.0.0 correlation, suggesting, instead a 12.9.0.0.0 correlation. The latter of these two dates does harmonise with Tepeu 1, as dated in the 11.16.0.0.0 correlation, however, while the statistical error of the former still allows for the same interpretation.

Unfortunately, the Early Classic Period (Tzakol ceramic sphere) is very poorly represented at Seibal and no samples from such a context could be obtained. The Late Preclassic (Chicanel ceramic sphere) is, on the other hand, well represented by structures and pottery at the site although we were unable to find appropriate materials for radiocarbon dating.

We appreciate the encouragement of W. F. Libby of UCLA. This work was supported by the National Science Foundation.

# Fever in the lizard Dipsosaurus dorsalis

Fever is considered to be a universal response of warm-blooded animals to endotoxins1. Although during a fever a mammal uses behavioural as well as physiological means to increase its body temperature<sup>2</sup>, it is not known whether fever develops in an animal such as a lizard which regulates its body temperature largely by behaviour. For example, the desert iguana (Dipsosaurus dorsalis) regulates its body temperature close to 38.5° C if placed in a chamber with a temperature gradient3. If this lizard is placed in a temperature chamber in which one end is heated to above the animal's lethal body temperature (50° C) and the other end is maintained at room temperature, the lizard regulates its temperature by moving back and forth between the two sides4. Under these conditions, one can determine its high and low set-points (Fig. 1). The central nervous control of temperature in an ectotherm, such as a lizard, and an endotherm, such as the rabbit, appears to be quite similar. For example, both possess a hypothalamus which is thermally sensitive<sup>5,6</sup>, and lesions in the posterior hypothalamus in both lizards4 and mammals<sup>7</sup> lead to an inability to maintain a high body temperature.

Because of the similarities in the central nervous control of thermoregulation in reptiles and mammals, and because fever in mammals is accompanied by major behavioural adjustments, we suspected that fever could be produced in a reptile. We now report that bacteria that produce fever in a rabbit will produce a similar fever in the lizard Dipsosaurus dorsalis.

Lizards weighing 25-60 g (Hermosa Reptile Farm, Hermosa, California) were housed in circular cages and fed meal worms, lettuce and water ad libitum. The cages and experimental chambers were kept on a 12-h light and 12-h dark photoperiod. The chamber was heated by a 250 W heat lamp which was also on a 12:12 cycle.

Experiments were carried out in a temperature-controlled room. Each lizard was placed in a wooden box (30 cm ×  $140 \, \mathrm{cm} \times 30 \, \mathrm{cm}$ ) of which one end was at the room temperature of 30° C and the other end at 50° C. This high temperature was provided by heating coils taped to the undersurface of the floor of one end of the box. The two sides of the box were separated by a small wire mesh bridge to provide a clear boundary between the two temperature extremes. A copper-constantan thermocouple covered with polyethylene tubing (PE 100) was placed about 3 cm into each lizard's cloaca and taped to its tail; this did not noticeably impair the movement of the lizards. Thermocouples were connected to a Honeywell Electronik 112 multipoint recorder which recorded the temperature of each lizard ( $\pm 0.1^{\circ}$  C) every 30 s.

Aeromonas hydrophila, Gram-negative bacteria pathogenic to reptiles and amphibians8, were grown on blood agar and killed by washing in 70% ethyl alcohol. They were then centrifuged and resuspended in physiological saline. The concentration of bacteria was determined by a turbidity test.

Lizards were allowed 1 d to adapt to the wooden box, and on the second day control data were recorded. On the third day either 0.2 ml of a solution containing 2 × 1010 bacteria per ml of saline or 0.2 ml of sterile physiological saline alone was injected into the heart using a 1.5-inch 26-gauge needle. Blood

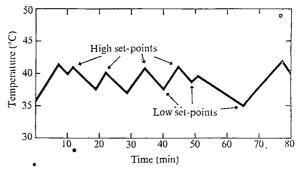

Fig. 1 Record of the cloacal temperature of Dipsosaurus dorsalis regulating its temperature in the wooden box in which the substrate at one end was maintained at 30° C and the other end at 50° C. At the high set-point, the lizard moved from the warm side of the chamber to the cool side. At the low set-point the lizard moved back to the warm side of the chamber. Data were recorded every 30 s. The high and low set-points, for any time period, represent the average of these points over that time period.

was redrawn into the syringe to ensure that the needle was in the heart. All injections were done at the same time of day to avoid possible effects of diurnal variations.

To determine whether increases in body temperature were due entirely to behavioural modifications, or whether an increased internal production of heat was part of the response, three lizards were given injections of bacteria identical to the above. They were then placed in a wooden chamber (14 cm  $\times$  30 cm  $\times$ 30 cm) which was held at 30° C. Cloacal temperatures were measured as before.

Four New Zealand white rabbits (Oryctolagus cuniculus) were used to determine whether A. hydrophila could also produce fever in mammals. The rabbits' tails were shaved and a thermocouple was inserted 10 cm into the rectum and taped to the tail. The rabbits were placed in a restrainer and allowed 1 h to acclimatise to room temperature (22° C). Then 0.2 ml of saline was injected into the marginal ear vein. After 1 h (control period), 1 ml of 3 × 10<sup>8</sup> bacteria per ml saline was injected into the marginal vein of the other ear.

In 10 lizards, given free choice of either the 50° C or 30° C environment, injection of 4 × 109 bacteria produced little increase in temperature during the first few hours. Body temperature increased approximately 2° C between the fourth and sixth hours (Fig. 2). The increases of the average high (41.1° C to 42.7° C) and low (37.4° C to 39.7° C) set-points were highly statistically significant (P<0.001 using paired sample analysis).

When the same concentration of bacteria was injected into three lizards maintained in a constant temperature chamber at 30° C, their temperatures did not change throughout the control and experimental periods. Injection of saline into nine lizards, given free choice of the warm or cool environment, produced no changes in high or low set-points (Fig. 2). Comparison of lizards injected with saline to those with A. hydrophila revealed a statistically significant increase in the high (P < 0.02)and low (P < 0.003) set-points during the second 3 h (Student's t test). Injection of saline into the four rabbits produced no increase in rectal temperature. Injection of the bacteria produced a fever with a latency of about 20 min and a mean maximum rise of 2.2° C within 3 h.

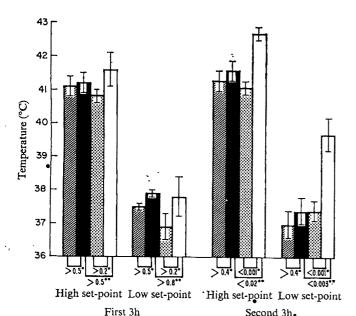

Fig. 2 Average high and low set-points ( $\pm$ s.e.m.) during control periods (day 2) and after intracardiac injection of 0.2 ml isotonic saline or 0.2 ml of 2  $\times$  10<sup>10</sup> Aeromonas hydrophila ml1- (day 3) into Dipsosaurus dorsalis. \*, Level of significance using paired sample analysis; †, level of significance using Student's t test. Hatched columns, control period before saline injections; solid columns, period after saline injections; stippled columns, control period before Aeromonas injections; open columns, period after Aeromonas injections.

These data indicate that a bacterium that causes fever in a rabbit has a similar effect in a lizard. Since the lizards could not increase their temperature in response to the bacteria when the ambient temperature was held constant, fever in these lizards cannot be developed by increased internal production of heat. The relatively long latency before the onset of fever in the lizards might be due to the lower metabolic rate of an ectotherm in comparison with that of an endotherm.

These results demonstrate that fever can be sustained by behavioural regulation in an ectotherm. Also, since the hypothalamic control over thermal responses in reptiles and mammals are similar4-6 and as we have shown, a similar concentration of bacteria will produce a similar increase in temperature in both a reptile and a mammal, we suspect a common origin for reptilian and mammalian fever. If this is true, then the ability to develop a fever existed before the time when evolutionary lines for mammals and reptiles diverged. This suggests that at least the behavioural component of fever had evolved by the late Palaeozoic or early Mesozoic, or perhaps even earlier. We cannot rule out the possibility, however, that fever might have independently and perhaps recently evolved in reptiles and mammals.

These findings also open new possibilities for ascertaining the adaptive value of fever. The question of whether fever is beneficial or harmful to the host has been difficult to resolve in mammals. Since the increase in body temperature in response to bacterial infection might have evolved in primitive reptiles, or even in amphibians, the adaptive value of fever might be revealed by a careful study of the role of the febrile response in these classes of vertebrates.

We thank Drs B. Cohen and D. Ringler and the Unit for Laboratory Animal Medicine for bacteria. We thank L. D'Alecy, D. Mouw and A. Vander for critically reviewing our manuscript.

### Dependence of juvenile hormone release from corpus allatum on intraglandular content

THE corpus allatum has been shown to be the source of chemically defined juvenile hormones in five different species of insect1-5. The release of juvenile hormone from active corpora allata is known to be a prerequisite for the rapid induction and promotion of vitellogenesis in adult female insects of several orders, including all tested members of the Orthoptera<sup>6,7</sup>. It is generally believed that temporal patterns of activity in the adult female corpus allatum are of prime importance in initiating and maintaining oocyte growth<sup>6,8</sup>.

Up to now the activity of the corpus allatum has been inferred from indirect observations such as glandular activity

after transplantation into a suitable host animal<sup>9</sup>, gland extirpation plus hormone replacement therapy<sup>10</sup> and measurement by bioassay of apparent titres of juvenile hormone in the haemolymph<sup>11,12</sup> and in freshly excised glands<sup>12</sup>. A direct, quantitative method for estimating the activity of the corpus allatum has recently become available, following the demonstration that the synthesis and release of juvenile hormone from corpora allata taken from adult female \$\mathcal{S}\$chistocerca gregaria can be rapidly measured in vitro by precise radiochemical procedures<sup>4,13</sup>. Here we deal mainly with the possible regulation of release of newly synthesised juvenile hormone using corpora allata from female \$S\$. gregaria during the first gonotrophic cycle. We show that at all times during sexual maturation it is the rate of synthesis of juvenile hormone and not the rate of release, which determines the endocrine activity of the glands.

To explore the relationship between the rate of synthesis of locust juvenile hormone, methyl 10,11-epoxy-3,7,11-tri-methyl-2,6-trans,trans-dodecadienoate (C<sub>16</sub>JH), the extent of its storage within the glands and its rate of release, freshly-isolated corpora allata were incubated in TC 199 medium containing methyl-14C-methionine for 2 h at 30°C with shaking. The medium was separated from the washed glands and both were analysed for radiolabelled C16JH content as previously described13. Observations were made on glands taken daily from adult female locusts between the ages of 3 and 12 d after fledging, during which period there are changes of approximately 400-fold in the rate of juvenile hormone release measured in vitro (S. S. T., and G. E. P., unpublished). We also carried out parallel measurements on glands incubated with optimal concentrations of C-23H-trans, trans farnesenic acid, an exogenous precursor known to stimulate directly the rate of juvenile hormone biosynthesis in these glands4. Thus, on each day of sexual maturation, we compared the steady state glandular content of C16JH with its rate of release from the glands, both in glands synthesising juvenile hormone spontaneously and in those whose rate of synthesis has been stimulated artificially with exogenous farnesenic acid. In this way we tested by direct observation, the alternative hypotheses that the naturally variable rates of release of hormone from the glands are the result either of direct regulation of the rate of biosynthesis, or of the direct regulation of the rate of release of newly synthesised hormone. Figure 1 shows the rates of release of hormone as a function of intraglandular content. For each day the points representing spontaneous activity and farnesenic acid-stimulated activity have been joined with a straight line, whose slope we term the 'release coefficient'. These slopes indicate the extent to which stimulating JH biosynthesis, by addition of farnesenic acid to the medium, alters the relationship between glandular content and rate of release. It can be seen that the data approximate a linear relationship of 'rate of release' on 'glandular content'; analysis shows that the regression line passes through the origin and has a slope of 2.7 h<sup>-1</sup>. Moreover, this mean regression is reflected in the 'release coefficients' of the various glands having these widely different spontaneous activities (mean = 2.83 h<sup>-1</sup>; s.d.  $\pm 1.00$ ). Although the variations in slope are small compared with the variations in spontaneous activity of the glands, the possibility existed that the observed variations in 'release coefficient' might have some functional relationship with the spontaneous in vitro activity of the glands. We have therefore compared these two parameters (Table 1) and regression analysis indicated a very weak correlation (slope = 0.046; s.d.  $\pm 0.023$ ) indicating that differences in 'release coefficient' are attributable to independent variations including experimental error.

Thus at all times during sexual maturation, both the rates of synthesis and release of juvenile hormone can be stimulated proportionately by the addition of farnesenic acid to the medium, such that the hourly release of newly-synthesised juvenile hormone is approximately equal to 2.7 times the steady state glandular content of the hormone. This seemingly simple relationship between the rate of release of juvenile

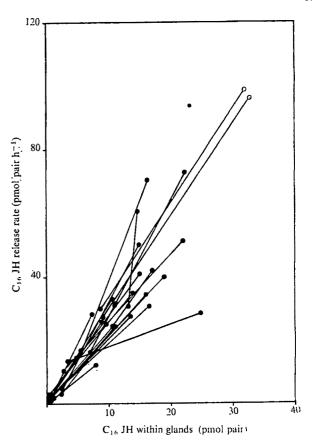

Fig. 1 The rate of release of C<sub>16</sub>JH relative to its concentration within the corpora allata. Each point represents the mean of two sets of observations on single pairs of glands from adult female locusts during the first gonotrophic cycle. The lines join observations from glands synthesising  $C_{1a}JH$  spontaneously and those stimulated with  $^3H$ -farnesenic acid on each given experimental day. In every case the rate of release from stimulated glands is higher than the spontaneous rate. Both the rate of release and the glandular content of hormone were monitored throughout the period of sexual maturation by incubation of glands for 2 h in TC 199 (20 mM HEPES) containing Ficoll (20 mg ml<sup>-1</sup>) and either <sup>14</sup>C-methionine (final specific radioactivity 36.7 mCi mmol<sup>-1</sup>) or <sup>14</sup>C-methionine plus <sup>3</sup>H-farnesenic acid (20 µM; specific radioactivity 25 mCi mmol<sup>-1</sup>). After incubation, individual pairs of glands were separated from the medium and both glands and medium were separately extracted with fifteen volumes of CHCl<sub>3</sub>:C<sub>2</sub>H<sub>6</sub>OH (5:1) after adjustment to pH 4.6 and addition of appropriate nonradioactive marker compounds. Extracts were analysed by thin layer chromatography (Merck F<sub>254</sub> silica gel) in ethyl acetate: benzene (25:75) followed by episcopic fluorescence quenching densitometry and scanning gas-flow radiometry. Radioactivity in  $C_{18}JH$  was quantified by liquid scintillation spectrometry. At all times the rate of release of juvenile hormone is determined by the glandular content of hormone. ( $\alpha = 0.0$  pmol h<sup>-1</sup> per pair of glands;  $\beta = 2.7$  h<sup>-1</sup>; r = 0.92).

hormone and the steady state glandular content, irrespective of the spontaneous activity of the glands, suggests that the export of juvenile hormone is governed by laws of simple physical diffusion. Although the route of export of juvenile hormone is not yet established, it has been proposed that this may involve diffusion out of the glands through a network of extracellular spaces.

Ultrastructural observations on the corpora allata of this <sup>14</sup> and other <sup>9,15</sup> insect species have led others to suggest an association between the release of juvenile hormone and observable changes in the subcellular architecture of the glands. It has been suggested that in the corpus allatum of Calliphora erythrocephala newly synthesised juvenile hormone accumulates initially in vacuoles associated with the agranular reticulum. These vacuoles eventually break down into lipid droplets

Table 1 Relation between rate of release of C<sub>16</sub>JH synthesised spontaneously and its 'release coefficient'

Rate of release of C <sub>16</sub> JH	Release coefficient	-
synthesised spontaneously	$R_{\mathrm{st}} - R_{\mathrm{sp}}$	Adult age
(pmol h <sup>-1</sup> per pair of glands)	$\overline{C_{\mathrm{st}}-C_{\mathrm{sp}}}^{*}$	(d)
29.90	3.28	9
16.70	5.11	12
14.63	2.92	8
12.09	3.80	10
10.40	2.11	8
4.70	2.16	9
4.40	3.68	10
3.08	2.34	7
2.80	2.64	7
2.03	1.95	6
1.83	1.75	12
1.80	2.07	6
1.80	3.88	4
0.80	2.85	5
0.44	2.86	. 6
0.43	2.30	5
0.14	2.01	5
0.11	2.93	4
0.07	3.15	6 4 5 5 5 5 4 4 3
0.05	2.88	3

Each value represents the mean of two separate sets of observations on single pairs of glands from animals of the age indicated. There is no correlation between spontaneous rate of hormone release and 'release coefficient' ( $\alpha = 2.59$ , s.d.  $\pm 0.21$ ;  $\beta = 0.046$ , s.d.  $\pm 0.023$ ;

\* $R_{\rm st} = C_{16}$ JH release rate of glands stimulated by addition of sh-farnesenic acid;  $R_{\rm sp} = C_{16}$ JH release rate of glands synthesising hormone spontaneously;  $C_{\rm st} = C_{16}$ JH content of glands stimulated by addition of sh-farnesenic acid;  $C_{\rm sp} = C_{16}$ JH content of glands synthesising hormone spontaneously.

within the cytoplasm and are then released into the haemolymph<sup>15</sup>. On the other hand, in Locusta migratoria, the fragmentation of the smooth endoplasmic reticulum is believed to be an important stage in the release of hormone from the glands9. It has also been reported that corpora allata of S. gregaria contain lipid droplets which increase in size towards the periphery of the cells<sup>14</sup>. It is difficult to reconcile the results presented here with any proposed mechanism of hormone release involving massive changes in the ultrastructural organisation of the cells, particularly since it is known that in S. gregaria newly synthesised juvenile hormone can be detected in the culture medium within 10 min of the addition of radiolabelled precursors<sup>13</sup>. Therefore we propose that the observed changes in the ultrastructure of cells of the corpus allatum reflect changes in their hormone synthetic capacity, rather than reveal the morphological basis of hormone synthesis, intracellular transport and release.

The possibility that storage of newly synthesised juvenile hormone may be an important facet of the normal endocrine function of the corpus allatum has never been directly tested in any species of insect. It is now clear that at no time during the course of rapid sexual maturation in the adult female desert locust do isolated corpora allata synthesise juvenile hormone and then fail to release it into the medium. Whether or not this also holds true in circumstances other than those of rapid sexual maturation remains to be seen.

We thank Dr F. A. Mellon for computer analysis of liquid scintillation spectrometry data and for regression analysis, and Dr A. F. White for <sup>3</sup>H-methyl farnesoate and reference compounds. S.S.T. acknowledges receipt of a National Research Council of Canada postdoctoral felfowship.

#### Choline transport by neuroblastoma cells in tissue culture

NEUROBLASTOMA cells in tissue culture have been used widely as an in vitro model for neural functions. Certain 'cholinergic' clones have raised choline acetyltransferase activities1, and all clones studied display a high affinity uptake system for exogenous choline<sup>2</sup>. Whereas low affinity  $(K_T \simeq 10^{-3} \text{ M})$  choline transport systems occur in various neural and non-neural mammalian tissues, high affinity ( $K_T < 10^{-5}$  M), sodiumdependent choline uptake in brain synaptosomes3,4 and the guinea pig intestine (C. B. Pert, and S. H. Snyder, personal communication) is restricted to cholinergic neurones. Efficient conversion of choline to acetylcholine, ionic requirements and sensitivity to inhibitors should uniquely distinguish the cholinergic transport system from those of similar affinity for choline which occur in many cultured mammalian cell lines. We have examined these properties of the choline transport system in cholinergic and non-cholinergic neuroblastoma clones.

The profiles for enzymes involved in the synthesis and degradation of acetylcholine are characteristic of each cloned neuroblastoma cell line (Table 1). The activities of choline acetyltransferase which we obtained are similar to other values previously reported for these lines<sup>1</sup>, although the N18 clone is

Table 1 Acetylcholinesterase and choline acetyltransferase activities of neuroblastoma cell lines

Cell line	Acetylcholinesterase	Choline acetyltransferase
	nmol per mg protein per min	nmol per mg protein per h
NS20 clone		6.50
N18 clone		3.71
N1E clone	TF. 7	n.d.
MIE CIOILE	7.	111-04-

n.d., Not detectable.

Neuroblastoma cells were obtained from Microbiological Associates (clone N18) or from Dr Arthur Blume (clones N1E and NS20). The nomenclature used for the clones is that of Amano et al.1. The lines were maintained by serial cultivation in Dulbecco's modification of Eagle's medium supplemented with 10% foetal calf serum. For enzyme assays and metabolic studies, the cultures were allowed to reach stationary phase, giving about  $2 \times 10^7$  cells per 75 cm<sup>2</sup> plastic flask (Falcon Plastics, Inc.). Acetylcholinesterase was measured by a contract of the property of modification of the method of Ellman et al.11 in which we use 1% Nonidet P-40 to solubilise the enzyme and assay activity at 35° C Choline acetyltransferase activity was determined by a standard technique12.

Table 2 Kinetic constants for choline transport by neuroblastoma cells

1	Cell line NS20 N18			NIE		
Constant $K_T$ (M × 10°) $V_{\text{max}}$ (M × 101° per min per mg protein)	Unstarved 20.7 19.8	Starved 4.5 21.2	Unstarved 17.1 38.9	Starved 3.5 11.2	Unstarved 10.2 2.8	Starved 2.1 3.0

Neuroblastoma cells of the clones indicated were grown to saturation in Linbro microwells (about 0.4 mg of protein or  $8 \times 10^5$  cells per well). Triplicate cultures were either incubated overnight in Hank's BSS to deplete the cells of choline and labile choline metabolites or they were merely washed twice with the buffer. For measurement of choline transport, cultures were exposed to 0.2 ml of Hank's BSS containing the appropriate concentrations of <sup>3</sup>H-choline (from Amersham Searle at a specific activity of 0.5 Ci mmol<sup>-1</sup>) for 4 min at 37° C and then quickly washed three times with ice-cold buffer. Cells were lysed by addition of 0.5 ml of distilled water, and radioactivity in the suspension was determined by scintillation counting in dioxane based phosphor. Choline accumulation was linear for nearly an hour in all three clones using both choline depleted cells and those maintained in medium containing choline. After a 1-h exposure to  $5 \times 10^{-5}$  M <sup>3</sup>H-choline, the concentration of labelled compounds within cells exceeded the radioactivity in the medium by a factor of 20. The kinetics of accumulation and cell/medium ratios were very similar to those reported for lymphoblasts *in vitro*<sup>7</sup>. It was estimated that at the highest choline concentration used, passive diffusion of choline into cells accounted for approximately 5-10% of the total uptake. After correction for diffusion, the data were plotted and linear regression lines calculated. The difference between  $K_{\rm m}$  values obtained with and without choline depletion is highly significant (P < 0.001) while the difference between the  $V_{\rm max}$  values is not (0.3 > P < 0.5)

apparently not 'inactive' in respect of synthesis of this enzyme. We consistently found higher cholinesterase activities in induced cultures of our clone N18 and lower activities in our clone N1E than are usually reported<sup>1,5</sup>, especially when cells of the N18 line were induced for acetylcholinesterase by leaving serum out of the growth medium<sup>6</sup>. These differences may be attributed to variations in the assay procedure or growth conditions and would not be expected to influence the results of the present study.

 $K_{\rm T}$  values for choline transport were determined in three clonal lines with and without previous choline depletion (Table 2). The affinities of the transport systems for choline in all three clones are quite similar and are increased about fivefold by choline depletion. The  $K_{\rm T}$  values for starved and unstarved cells are similar to those reported for hepatoma cells by Plagemann<sup>8,9</sup> and for starved neuroblastoma cells<sup>2</sup>. Experiments using choline concentrations as high as  $2\times 10^{-3}$  M did not reveal a  $K_{\rm T}$  of lower affinity in depleted cells so it must be assumed that there is only one transport system for choline in neuroblastoma cells and that its affinity depends upon previous exposure of the cells to choline.

 $V_{\rm max}$  values for the adrenergic clone (N1E) indicate a lower capacity of its transport system, a reflection, perhaps, of smaller surface area as a result of relatively poor axonation by this clone. In general, the data are consistent with those obtained using hepatoma cells. The  $V_{\rm max}$  values with and without choline depletion are similar to those previously observed in neuroblastoma cells. Double reciprocal analysis of rates of uptake by each of the 3 clones indicated competitive kinetics. This apparent competitive inhibition cannot be due to isotope dilution by leakage of non-radioactive free choline from unstarved cells since there is not sufficient intracellular free choline to produce the observed effect.

We then studied the fate of choline transported into the various clones (Table 3). Only very small amounts of choline were detected in any of the clones. This is in marked contrast to brain cholinergic synaptosomes which accumulate choline and acetylcholine in roughly equal proportions<sup>3,4</sup> when exposed to a similar concentration of free choline. The formation of small quantities of acetylcholine was, however, significantly dependent on the activity of intracellular choline acetyltransferase (Table 1), being low in the adrenergic clone (N1E), intermediate in the 'inactive' clone (N18) and highest in the cholinergic clone (NS20). The major radioactive product in all 3 clones was phosphorylcholine which, as suggested by data obtained with the long incubation period, was capable of serving as a precursor of phosphatidyl choline. Subsequently, more detailed experiments showed that the free choline could be chased first into phosphorylcholine and then into phosphatidyl choline.

Disposition of choline in this manner would be expected of

cells lacking either the 'high affinity' choline transport system itself or proper coupling to choline acetyltransferase. To distinguish between these possibilities, we examined the effects of various known inhibitors of transport on uptake and metabolism of choline. Synaptosomal uptake of choline at low concentrations is sensitive to hemicholinium<sup>3</sup> and dependent on sodium<sup>4</sup>. As Table 4 shows, the neuroblastoma transport system is not inhibited by even a high concentration of hemicholinium and is independent of sodium. The distribution of choline among its various metabolites is also unaffected by these treatments. It seems that although cultured neuroblastoma cells have a transport system for choline, it is similar to that found in many types of non-neural cells and does not display the characteristics associated with the 'high affinity' uptake system unique to brain cholinergic synaptosomes.

Table 3 Fate of choline in neuroblastoma cell lines

	4-min Incorporation			12-h Incorporation		
	N18	NS20	NIE	N18	NS20	NIE
Choline	3.6	2.8	4.1	0.5	1.0	1.3
Acetylcholine	0.2	0.5	0.1	0.1	0.4	0.1
Phosphorylcholine	96.2	96.7	95.9	72.2	71.0	85.2
Phosphatidyl choline	0.1	0.1	0.1	27.2	27.7	13.5
Total	100.1	100.1	100.2	100.0	100.1	100.1

Neuroblastoma cells were grown to confluence in 75 cm<sup>2</sup> culture flasks (Falcon Plastics, Inc.) and depleted of choline by incubation overnight in Hank's BSS containing an irreversible inhibitor of AChE<sup>6</sup>.  ${}^{3}\text{H-choline}$  was added at a final concentration of 5  $\times$  10<sup>-5</sup> M and incubation continued for the indicated times. Monolayers were washed three times with ice-cold buffer and then scraped off into 0.5 ml of ice-cold 95% ethanol containing 0.2% acetic acid, 2 mM acetylcholine, 3 mM choline and 0.1 mM neostigmine<sup>3</sup>. The suspension was homogenised thoroughly and the debris pelleted at 1,000g for 10 min. The pellet was re-extracted with acid ethanol and then with ethanol-ether (1:1). The ethanol-ether extract was shown chromatographically to contain mostly phosphatidyl choline and a very small amount of phosphoryl choline<sup>13</sup>. Phosphoryl choline, acetylcholine and free choline were all soluble in the acid-ethanol extract but could be separated by high voltage paper electrophoresis14. Since phosphoryl choline remained at the origin in our electrophoretic system, its identity was confirmed by thin layer chromatography". In 4 min, an average of 4,000 c.p.m. per mg protein were incorporated, increasing to approximately 10,000 c.p.m. per mg protein after 12 h. Uptake by the various lines was quantitatively similar so, to facilitate comparisons, data are expressed as % total c.p.m. recovered. Assuming that complete equilibration of the acetylcholine and phosphorylcholine pools with exogenous labelled choline occurred during 12-h incubation, then the intracellular acetylcholine concentration in NS20 can be calculated to be about 10-7 M and that of phosphorylcholine about  $2\times10^{-6}$  M. Under the conditions of these incubations, greater than 99% of acetylcholinesterase activity was inhibited. In the absence of an acetylcholinesterase inhibitor even less acetylcholine was recovered, but an accurate determination of the acetylcholine concentration under these conditions could not be made.

Table 4 Effect of various inhibitors on choline transport

Inhibitor	Choline uptake
	(% of control)
None	100
Hemicholinium (0.1 mM)	131
Na <sup>+</sup> replaced by Li <sup>+</sup>	81
Na <sup>+</sup> replaced by sucrose (0.25 M)	66
Ca <sup>2+</sup> replaced by Mg <sup>2+</sup>	93
2,4-dinitrophenol (1 mM)	40
Ouabain (Î mM)	38
Incubation at 0° C	10

Neuroblastoma cells (NS20 clone) were grown to confluence in 75 cm² plastic flasks and depleted of choline metabolites as described for Table 3. The cultures were preincubated with the anticholinesterase agent and the indicated metabolic inhibitor in Hank's BSS for 15 min. Then  $2 \times 10^{-3} M$  <sup>3</sup>H-choline was added and after a further 15 min incubation the cells were collected as described in Table 2.

As would be expected for any energy-dependent cellular process, uptake is inhibited by low temperature and 2,4dinitrophenol. But this should not be interpreted as evidence. that choline is taken into neuroblastoma cells by active transport. We have never observed an intracellular choline concentration greater than that in the medium and inhibition of transport by such nonspecific agents could have other explanations. In erythrocytes there is a facilitated diffusion system for choline10 and we have no evidence against the operation of such a mechanism in neuroblastoma. These inhibitor effects do not eliminate the possibility that the characteristic properties of cholinergic choline transport emerge when a universal uptake system is coupled to choline acetyltransferase. If coupling were absent in neuroblastoma cells, choline kinase and acetyltransferase could compete for their common substrate.

Although the absence of the brain synaptosomal high affinity choline transport system may simply be correlated with the absence of synapses in neuroblastoma cultures15, there are other explanations of our data. In particular, synthesis of choline acetyltransferase may not be an expression of more generalised cholinergic potential of the NS20 clone. This view is supported by the existence of acetylcholine receptors in neuroblastoma cells16, a finding that suggests a postganglionic origin for the cells and seems incompatible with the concomitant presence of cholinergic synaptic structures. Nevertheless, the generation of a high affinity uptake system possessing such properties as preferential synthesis of acetylcholine and sensitivity to appropriate inhibitors could provide a convenient biochemical tool for investigating the differentiation of neuroblastoma cells in vitro.

# Binding of interferon to gangliosides

RECENT evidence suggests that the antiviral action of interferon is triggered by interaction with the cellular membrane. Mouse interferon covalently bound to Sepharose beads (IF-Sepharose) retains its antiviral potency and only direct contact with these particles produces the antiviral effect<sup>1,2</sup>. Preincubation of mouse L cells with *Phaseolus vulgaris* phytohaemagglutinin (PHA) blocks interferon action3. The inhibitory action of PHA can be almost completely reversed by washing PHA-treated cells with fetuin, a glycoprotein of high affinity for this plant lectin3. These data suggest that membrane sites interacting with interferon are carbohydrate-containing molecules that bind to PHA, although other explanations for the inhibitory action of PHA based on nonspecific steric or charge effects might be possible. To substantiate further that glycoside-containing membrane components bind to interferon, we have investigated the effect of gangliosides on interferon binding and

As Table 1 shows, preincubation of IF-Sepharose with a ganglioside mixture from bovine brain completely blocked antiviral activity. When tested individually, mono- as well as diand trisialogangliosides were inhibitory. The concentration in the preincubation mixture resulting in maximal inhibition of antiviral activity was lowest for  $G_{M2}$  and  $G_{T1}$ , suggesting somewhat stronger binding of these two gangliosides. Thinlayer chromatography on silica plates in chloroform-methanolwater (65:45:9) followed by resorcinol spray4 revealed one band for  $G_{M2}$ , but showed that commercial  $G_{M1}$ ,  $G_{D1\,a}$  and  $G_{T1}$ were somewhat contaminated with other gangliosides although free of  $G_{M2}$ . In separate experiments using  $G_{M1}$ ,  $G_{D1a}$  and  $G_{T1}$ which were 82-87% pure, essentially similar results were obtained, though  $G_{M1}$  and  $G_{D1a}$  appeared slightly less inhibitory.  $G_{M3}$ , a mixture of the acetyl and the glycolyl neuraminic acid derivatives, was only tested at one concentration because of the small amount available. Its inhibitory action appeared slightly less than that of  $G_{M2}$  and  $G_{T1}$ , but more than that of the other two gangliosides. In our determinations of viral yield only differences greater than twofold were considered significant. Therefore, although Table 1 compares µg quantities of gangliosides instead of µmol, the accuracy of the assay does not allow conclusions based on molecular weight differences of individual gangliosides. Inhibition of IF-Sepharose by individual gangliosides was the same regardless of whether preincubation was carried out for 1 h or 18 h. When the temperature of the preincubation mixture was varied, however, there was a consistent increase of the inhibitory effect of gangliosides with increasing temperatures. Thus, EMC yield by plaque-forming units (PFU) in response to IF-Sepharose preincubated with mixed gangliosides at 4° C was one-third of that found after preincubation at 37°C. Washing ganglioside-treated IF-Sepharose with PHA solutions partially reversed ganglioside inhibition, suggesting that PHA and interferon have common binding sites (Table 2). It was not possible completely to restore antiviral activity, however, indicating that under the conditions

Table 1 Inhibition of interferon-Sepharose by gangliosides

Interferon covalently bound to Sepharose (IF-Sepharose), prepared as described previously<sup>1,2</sup>, was treated with gangliosides by incubating 5 × 10<sup>4</sup> beads with 0.4 ml ganglioside solution in PBS for 75 min at 25° C. The beads were then washed once with 4 ml PBS and suspended in 1 ml of Eagle's minimal essential medium plus Hanks salts without serum (MEM). The gangliosidemixture was obtained from bovine brain (Sigma, type III). Individual gangliosides were obtained from Supelco Inc. Mouse L cells were cultivated in 35 mm plastic dishes (5 × 10<sup>5</sup> cells per dish) in MEM, containing 10% calf serum. After removal of medium the cells were incubated for 5 h at 37° C with a 1-ml suspension of IF-Sepharose or control Sepharose 4-B in MEM at a ratio of one bead per 10 cells. After removal of the beads, the cells were challenged with encephalomyocarditis virus (EMC) at a multiplicity of infection of 0.1. Viral yield was determined after 16 h of incubation at 37° C by haemagglutination of human red blood cells of type 0 in serial twofold dilutions of virus suspensions 10. The numbers represent the reciprocal of the highest dilution that showed haemagglutination. The individual gangliosides were designated according to Svennerholm 11. Numbers in brackets represent experiments in which control Sepharose 4-B was used instead of IF-Sepharose. ND, Not done.

Table 2 Effect of PHA on ganglioside inhibition of interferon-Sephanose

	interferon-Sepharose	e	
Ganglioside in preincubation mixture	Viral yield without ganglioside pretreat- ment of IF-Sepharose	ganglion ment of	yield after side pretreat- IF-Sepharose A After PHA

mixture (400 μg)	64	4.096	512/1,024
$G_{M2}$ (80 µg)	32/64	2,048	512
$G_{M1}$ (200 µg)	32/64	2,048	512
$G_{D1a}$ (200 µg)	32/64	1,024	512
$G_{T1}$ (80 µg)	32/64	2,048	512

After treatment of IF-Sepharose beads with gangliosides as described under Table 1, they were suspended in 0.3 ml of PHA (phyto-haemagglutinin from *Phaseolus vulgaris*, M form, Grand Island Biological Co.) at a protein concentration of 4.1 mg ml<sup>-1</sup>. After incubation for 60 min at 25° C the lectin solution was removed; the beads were washed once with 4 ml PBS, and suspended in 1 ml MEM without serum. Further experimental details were as described under Table 1.

used the affinity of gangliosides for interferon is greater than for PHA. Preincubation of L cells with gangliosides did not result in stimulation of the antiviral effect of interferon, as might be expected if gangliosides became incorporated into the cell membrane to produce additional receptor sites. Such stimulation of activity was observed with cholera toxin $^5$ , which has been shown to bind strongly to  $G_{M1}$  (ref. 6).

Incubation of interferon solutions with gangliosides bound covalently to a Sepharose-polylysine copolymer as described by Cuatrecasas resulted in complete adsorption of antiviral activity to these beads (Table 3). In contrast, under identical conditions control beads that only contained covalently bound polylysine did not bind interferon to any great extent. Binding of interferon to Sepharose-bound gangliosides was prevented by preincubation of these beads with PHA, in accord with previous results suggesting that PHA and interferon bind to common constituents on the cell membrane3. Washing PHAtreated ganglioside beads with fetuin, a protein of known affinity for PHA which reversed PHA inhibition of interferon action3, failed to restore measurable interferon binding to ganglioside beads, even at a concentration of 60 mg ml<sup>-1</sup>. It appears, therefore, that PHA has a higher affinity for Sepharosebound gangliosides than for fetuin in solution. Ganglioside-Sepharose beads also completely inhibited the action of soluble interferon, as Table 4 shows.

Gangliosides are common constituents of cellular membranes. The occurrence of disialoganglioside  $(G_{D1})$  and haematoside  $(G_{M3})$  in the cell membrane of L cells has been reported. Inhibition of mouse interferon action by preincubation of

Mouse interferon was prepared by induction of mouse L cells with ultraviolet-irradiated Newcastle disease virus in serum-free MEM plus Earle's salts as described before<sup>12</sup>. Crude interferon solutions were concentrated tenfold by pressure dialysis at pH 3 and used as such after changing the pH to 7. They contained 0.2 mg ml<sup>-1</sup> protein<sup>13</sup>. Polylysine (molecular weight 30,000, Sigma) was coupled to CNBr-activated Sepharose (Pharmacia) as described by Sica et al.<sup>14</sup>. Mixed gangliosides from bovine brain (type III, Sigma) were attached to polylysine-Sepharose as described by Cuatrecasas7. Covalently bound gangliosides correspond to 0.15 mg ml<sup>-1</sup> packed beads, as judged from the amount of carbohydrate in the soluble portion of the reaction mixtures after completion of the reaction15. In the experiments with PHA, 0.2 ml of packed beads was incubated for 30 min with 0.5 ml lectin solution (4.1 mg ml<sup>-1</sup> protein, see Table 2) for 30 min at 25° C. They were then washed twice with 1 ml of 1 M NaCl and twice with 1 ml of PBS. In each of the experiments listed 0.2 ml packed beads (washed twice with 1 ml of NaCl and twice with 1 ml of PBS immediately before use) were suspended in 0.5 ml of interferon solution and incubated for 45 min at 25° C with occasional stirring. The supernatant of the beads was collected, and the beads were washed twice with 1 ml of 1 M NaCl and twice with 1 ml of PBS. Original supernatant and washings were combined and the interferon titre was measured by determining the cytopathic effect in serial twofold dilutions on mouse L cells after infection with vesicular stomatitis virus (VSV). Control beads represent polylysine-containing beads before ganglioside attachment. In the control experiment without beads interferon solution was incubated alone and diluted with corresponding amounts of 1 M NaCl and PBS. The numbers represent the reciprocal of the dilution of combined supernatants and washings showing a cytopathic effect of 50%.

L cells with PHA suggests involvement of carbohydrate-containing cell membrane constituents in interferon binding and/or action<sup>3</sup>. Our data show binding of interferon to gangliosides and inhibition of interferon action by exogenous gangliosides. They also demonstrate that inhibition by and binding to gangliosides is partially or completely reversed by PHA, in accord with our previous results<sup>3</sup>. Binding to gangliosides has been shown for certain toxins, like cholera toxin and tetanus toxin, for hormones like seretonin<sup>6</sup>, and for viruses like Sendai<sup>9</sup>. Our data suggest that binding to gangliosides might also play a role in interferon action *in vivo*.

Table 4 Inhibition of interferon activity by ganglioside-Sepharose beads

A. A	Bead to	Viral yield (PFU m <sup>-1</sup> ×10 <sup>-6</sup> )			
Beads used	cell ratio			Interferon adde	
		I "	II	I	II

Control beads	1:10	800	ND	5	2
Ganglioside beads	1:10	800	ND	200	170
Control beads	1:20	ND	ND	ND	2
Ganglioside beads	1:20	ND	ND	ND	32

Polylysine-Sepharose (control) or ganglioside-Sepharose beads prepared as described under Table 3 were suspended in 1 ml of MEM without serum and layered on to mouse L cells in 35 mm plastic Petri dishes (5×10<sup>5</sup> cells per dish). Mouse interferon prepared as described under Table 3 was added and the cells were incubated at 37° C for 24 h. After removal of medium (derivatised Sepharose beads remained tightly attached to the cells) the cells were infected with VSV at a multiplicity of infection of 0.1 and further incubated for 16 h at 37° C. Viral yield was measured directly by determination of plaqueforming units (PFU). I and II represent two different sets of experiments. ND, Not done.

We thank Drs C. Chany, B. Galliot and M. J. Chevalier for IF-Sepharose and Drs Grossberg and Jameson for L cells and virus; we thank them all for advice and encouragement. We also thank Drs W. E. van Heyningen and S. Hakomori for gangliosides  $G_{M1}$ ,  $G_{D1a}$  and  $G_{T1}$ , and  $G_{M3}$ , respectively. This work was supported by grants from the American Cancer Society, Milwaukee Division, and the United States National Science Foundation. H.A. is a recipient of a career development award from the National Institute of General Medical Sciences.

#### Evidence for ATP action on the cell surface

It seems that Mg2+-ATPase (EC 3.6.1.3) and 5'-nucleotidase (EC 3.1.3.5) are prevalent plasma membrane marker enzymes in eukaryotic cells1. Our studies on the 'sidedness' of plasma membrane macromolecules suggested that the two enzymes function as ecto-enzymes<sup>2</sup>, although the substrates presumably were not present on the cell surface. We assumed that the substrates were present, but obscured within the intercellular spaces and by rapid metabolism. The specificity of the ecto-ATPase is low but we suspected that translocated cytoplasmic ATP might be a primary substrate.

We have recently obtained evidence in tissue cultures for apparent ATP translocation from the cytoplasm into the medium (unpublished data). Reports by McIlwain et al. that adenosine, and to a lesser extent adenylates, were released from electrically stimulated brain slices support this possibility<sup>3-5</sup>. Pull and McIlwain had speculated4 that ATP was the source of the released adenosine. We postulated that the translocation of cytoplasmic ATP might be part of a common physiological phenomenon. During a study of the effects of ATP application to the membrane surface I have now found that the addition of ATP to monolayer cultures of mammalian cells produces a biphasic change in membrane permeability. In situ this event may be initiated by the translocation of cytoplasmic ATP and terminated by ecto-nucleotidephosphoesterhydrolases.

Changes in membrane permeability were measured by determining the extrusion of isotopic ions from pulse labelled monolayer tissue cultures. I shall discuss the permeation of isotopic species because measurements of net fluxes have not been made yet. The basic methodology was briefly as follows. Established tissue culture cell lines were grown in 250 ml Falcon flasks in the appropriate medium. When the cultures reached confluency they were exposed for 2 h to 5 ml of medium containing <sup>32</sup>P<sub>1</sub>, <sup>42</sup>K+ or other isotopic compounds. After removal of the isotopic medium by several brief rinses, the cultures were superfused with 4 ml of serum-free medium at 37° C in an air/ CO<sub>2</sub> atmosphere (95/5, v/v). During incubation the flasks were rotated horizontally once every 150 s for 6 s at 50 r.p.m. to provide stirring action. Extrusion of isotopic species was measured by sampling the medium at intervals and by scintillation counting. Protein content of the cultures was determined in NaOH digests according to Lowry et al.6.

Using <sup>32</sup>P pulse labelled cultures of mouse fibroblasts (L929). HeLa cells (human choriocarcinoma) or KB cells (human carcinoma of the nasopharynx) I found that 32P efflux into the medium increased significantly when ATP reached about 5×10<sup>-4</sup> M. In monolayer cultures of neonatal Syrian hamster astrocytes, the effect of ATP is particularly evident and typical dose responses are illustrated in Fig. 1. When the superfusate

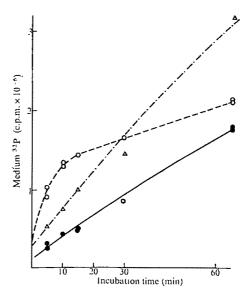

Fig. 1 Effect of medium ATP concentration on 32P extrusion of pulse labelled NN astrocyte cultures. Cultures labelled with <sup>32</sup>P<sub>1</sub> for 2 h, rinsed three times and superfused with Hanks' minimum essential medium containing ATP as indicated. Curves show cumulative  $^{32}P$  in medium.  $\triangle$ ,  $5 \times 10^{-3}$  M;  $\bigcirc$ ,  $1.2 \times 10^{-4}$  M; control.
